Renovation explicit dynamic procedures by application of Trujillo algorithm

H. Hashamdar*, Z. Ibrahim, M. Jameel and H. B. Mahmud

Department of Civil Engineering, University of Malaya, Kuala Lumpur, Malaysia.

Accepted 31 December, 2010

In this paper, a Trujillo algorithm method for the exact solution of nonlinear explicit dynamic problems is developed. This method associates numerical techniques and it is applied to determine the natural frequencies of structures. The numerical predictions of the natural frequency are compared to analytical and experimental results. There was no direct method available for solving such a problem efficiently in the case of explicit dynamic analysis. The Trujillo algorithm is an indirect method and the approach is based upon the principle of conservation of energy. It is believed that the proposed method provides a powerful engineering tool in the analyzing of structures.

Key words: Nonlinear dynamic response, optimization of energy, explicit dynamic analysis, finite element method, vibration, perturbation technique, analyzing modal, Trujillo algorithm method.

INTRODUCTION

There are three sources of nonlinearity in structural mechanics simulation:

(i) Material nonlinearity
(ii) Boundary nonlinearity
(iii) Geometric nonlinearity

Geometric nonlinearity is related to changes in the geometry of the model during the analysis (Stefanou, 2009).

Cable structures are very light and flexible and they undergo appreciable deflections when subjected to external loading. Since all the main load-carrying members in cable structures are usually in tension, if the tip deflection is small, the analysis can be considered as being approximately linear. However, if the tip deflection is large, the shape of structure and, hence, its stiffness changes, then, structural mechanism will belong to nonlinearity behavior. Thus, cable structure belongs to geometrically nonlinearity groups (Huu-Tai, 2010).

Although a number of method have been developed for dynamic response analysis of structural system, but there are only a few methods which can be used for nonlinear dynamic response analysis.

Tension roof structures are analyzed for static loads and their dynamic response is checked to ensure that the design provides sufficient safety and structural

serviceability. Although cable structures, under service loads, exhibit non-linear behavior, recent developments on computing methods have made it possible to carry out the analysis with great accuracy (Jian, 2007; Laie, 2010).

**EQUATION OF MOTION FOR A SYSTEM**

The cable structure is a multi degree system and the equation of motion for a multi degree of freedom (MDOF) system can be written as:

\[
M \dddot{x} + C(t) \ddot{x} + K(t) x = P(t) \tag{1}
\]

where

\[
M = \text{Mass matrix} \\
C(t) = \text{Damping matrix} \\
K(t) = \text{Stiffness matrix}
\]

\[
x = \text{Displacement vector} \\
x' = \text{Velocity vector} \\
x'' = \text{Acceleration vector} \\
P(t) = \text{Load vector}
\]

The assumption of a constant mass in the case of both MDOF systems is arbitrary as it could be represented as a time varying quantity.

Since \( m \) is a non-zero constant value, both sides of Equation (1) can be divided by \( m \), and for

\[
P = \frac{c}{m} \\
Q = \frac{F}{m}
\]

Equation (1) can be written as:
The mathematical solution of Equation (2) depends on the values of P, Q and F. Equation (2) is a linear differential equation if P and Q are independent of x and remains so even if P and Q are functions of t.

The solution is normally given in the form \( x = f(t) \) and gives exact values of x for any t once f(t) is defined. When P and Q are functions of x, Equation (2) becomes non-linear (Liqus, 2003).

For such equation the solution cannot be expressed in functional form and it is necessary to plot or tabulate to solution curve point by point, beginning at \((t_0, x_0)\) and then at selected intervals of t, usually equally spaced, until the solution has been extended to cover the required range. Thus the solutions of non-linear equations require a step-by-step approach and are normally based on the use of interpolation or finite difference equations. The independent variable t is divided into equal intervals \( \Delta t \), over the range of the desired solution. Thus the variables after \( n \) and \( (n+1) \) intervals are given by \( t_n = n \times \Delta t \) and \( t_{n+1} = (n+1) \times \Delta t \) respectively. At time \( t_n \), it is assumed that the values of all the parameters are known as well as the values for same parameters at all previous intervals \( (n-1),(n-2) \),....,\( 0 \). At time \( t_{n+1} \), it is assumed that the values of the variable parameters are not known and that the purpose of the analysis is to find the value of \( x_{n+1} \) (in the case of MDOF system, \( X_{n+1} \)) and its derivatives which satisfy

\[
M\dddot{X}_{n+1} + C\ddot{X}_{n+1} + K\dot{X}_{n+1} + \dot{R}_g = R
\]

At time \( t_n \) and time \( t_{n+1} = t_n + \Delta t \) the condition of dynamic equilibrium requires respectively that:

\[
m\dddot{x}_n + c_\alpha x'_n + k_\alpha x_n = p_n
\]

and

\[
m\dddot{x}_{n+1} + c_\alpha x'_{n+1} + k_\alpha x_{n+1} = p_{n+1}
\]

\[
X_{n+1} = X_n + \Delta X
\]

\[
X'_{n+1} = X'_n + \Delta \dot{X}
\]

\[
X''_{n+1} = X''_n + \Delta \ddot{X}
\]

\[
C_{n+1} = C_n + \Delta C
\]

\[
K_{n+1} = K_n + \Delta K
\]

Equation (5) may be written as

\[
M\Delta X_{n+1} + C\Delta x_{n+1} + K\Delta x_{n+1} + \dot{R}_g = R
\]

Evaluation of these expressions at the end of the time interval when \( t=\Delta t \) leads to the following expressions for the incremental velocity and displacement (Ghafari, 2008):

\[
\Delta \dddot{x} = \frac{6}{\Delta t} \Delta x - \frac{6}{\Delta t} \Delta \dot{x}_n - 3 \dddot{x}_n
\]
\[ \Delta \dot{x} = \frac{3}{\Delta t} \Delta x - 3 \frac{\Delta \dot{x}}{2} \]  

(8b)

In general it has been found to be convenient to use the incremental displacement as the basic variable and hence the \( \Delta x \) and \( \Delta \dot{x} \) in terms of \( \Delta x \). Rearranging Equations (8a) and (8b) yields.

\[ \Delta x = x_n \Delta t + \frac{1}{2} \Delta \dot{x} \Delta t \]  

(9a)

\[ \Delta \dot{x} = \frac{\Delta}{\Delta t} \Delta x + \frac{\Delta \dot{x}}{6} \Delta t^2 \]  

(9b)

Substitution of Equations (9a) and (9b) into Equation (7) and assuming \( K \) and \( C \) remain constant during the time interval leads to:

\[ \left( m \frac{6}{\Delta t} \Delta x + \frac{3}{\Delta t} \Delta \dot{x} + k_n \right) \Delta x = m \left( \frac{6}{\Delta t} \Delta x_n + \frac{3}{\Delta t} \dot{x}_n \right) + C_n \left( 3 \frac{\Delta \dot{x}}{2} + \frac{\Delta t}{2} \ddot{x} \right) + R \]  

(10)

TRUJILLO'S METHOD

Trujillo presented an explicit algorithm for the dynamic response analysis of structural systems. For linear undamped systems the method was shown to be unconditionally stable. An algorithm based upon the Trujillo's method has been developed for non-linear systems by Thomas (Thomas, 1981) but does not take into account the effect of damping.

The Trujillo algorithm

Trujillo splits the stiffness and damping matrices into upper and lower triangular forms, as indicated below, by the subscripts \( U \) and \( L \) respectively and presents, without giving the development of the equations, the following algorithm which is divided into a forward and a backward substitution.

Forward substitution:

\[ \dot{X}_{n+\frac{1}{2}} = \left[ X_{n+\frac{1}{2}} - X_n \right] \frac{4}{\Delta t} - \dot{X}_n \]  

(12)

Backward substitution:

\[ X_{n+1} = \left[ M + \frac{\Delta t^2}{2} C_U + \frac{\Delta t^2}{8} K_U \right]^{-1} \]  

\[ \left[ M + \frac{\Delta t}{2} C_U - \frac{\Delta t^2}{8} K_L \right] X_{n+\frac{1}{2}} + \frac{\Delta t}{2} \dot{X}_{n+\frac{1}{2}} + \frac{\Delta t^2}{16} \left[ P_{n+1} + P_n \right] \]

(13)

\[ \dot{X}_{n+1} = \left[ X_{n+1} - X_{n+\frac{1}{2}} \right] \frac{4}{\Delta t} - \dot{X}_{n+\frac{1}{2}} \]  

(14)

An advantage of this algorithm is that, since it is restricted to the use of diagonal mass matrices only, the coefficient matrices of \( X_{n+\frac{1}{2}} \) and \( X_{n+1} \) are obtained respectively in upper and lower triangular forms. Thus the solution of the equations at time \( t_{n+\frac{1}{2}} \) is reduced to forward and at time \( t_{n+1} \) to backward substitution only. The Trujillo suggests two ways of splitting the stiffness and damping matrices.

The first is a symmetric splitting which satisfies the conditions:

\[ K_L + K_U = K \quad ; \quad K_L = K_U^T \]  

(15)

and

\[ C_L + C_U = C \quad ; \quad C_L = C_U^T \]  

(16)

The second way differs from the first only by the manner in which the diagonal elements are distributed. Trujillo (1977), who extended Trujillo's work to apply to non-linear systems, but excludes damping and thus reduces the equilibrium equations at the \( n^{th} \) step to,

\[ M \ddot{X}_n + R_n = P_n \]  

(17)

where \( R_n \) is internal force vector, and presents the following algorithm for the middle and the end of step:

\[ \dot{X}_{n+\frac{1}{2}} = \left[ M + \frac{\Delta t^2}{8} K_L \right]^{-1} \left[ M - \frac{\Delta t^2}{8} K_L \right] \dot{X}_n + \frac{\Delta t^2}{16} \left[ P_{n+1} + P_n \right] \]  

(18)
Non-linearity is taken into account by updating the stiffness matrix at the end and if necessary also at the middle of each time step (Trujillo, 1977).

Expression total potential energy

The total potential energy is written as:

\[ W = U + V \]  \hspace{1cm} (22)

where

- \( W \) = the total potential energy
- \( U \) = the strain energy of the system, and
- \( V \) = the potential energy of the loading.

Taking the unloaded position of the assembly as datum,

\[ W = \sum_{n=1}^{m} U_n + \sum_{j=1}^{J} \sum_{i=1}^{3} F_{ji} X_{ji} \]  \hspace{1cm} (23)

where

- \( m \) = Total number of members,
- \( J \) = Total number of cable joints,
- \( F_{ji} \) = External applied load on joint \( j \) in direction \( i \), and
- \( X_{ji} \) = Displacement of joint \( j \) in direction \( i \).

The condition for structural equilibrium is that the total potential energy of the system is a minimum, that is, \( \partial W / \partial X_{ji} = 0 \) \hspace{1cm} (24)

The correct value of \( X \) for which \( W \) is a minimum, that is, \( g=0 \) can now be found by the iterative process

\[ X_{ji(k+1)} = X_{ji(k)} + S_{(k)} V_{ji(k)} \]  \hspace{1cm} (25)

where the suffices \( (k) \) and \( (k+1) \) denote the \( (k) \)th and \( (k+1) \)th iterate, respectively and;

\[ V_{ji} \] = the element of the direction vector, and \( S_{(k)} \) = the steplength which defines the position along \( V_{ji(k)} \) where the total potential energy is a minimum.

The expression for \( V_{ji} \) given by:

\[ V_{ji(k)} = -g_{ji(k)} + \sum_{j} \sum_{i=1}^{3} g_{ji(k-1)} g_{ji(k)} V_{ji(k-1)} \]  \hspace{1cm} (26)

The stationary point in the direction of descent can be found by expressing the total potential energy as a function of the step length along \( V_{ji} \). Thus the required value of \( S_{(k)} \) can be determined by the condition (Uksun, 2009).

\[ \partial W_{(k)} / \partial S_{(k)} = 0 \]  \hspace{1cm} (27)

In the convergence energy the iteration and tolerance are not required and the kinematic condition at one increment to calculate the kinematic condition at the next increment.

Numerical and experimental testing

The development of a mathematical control to ensure stability when using larger time steps is desirable. The use of larger time steps would mean that the starting point at the beginning of each time step would be further removed from the position where the total potential dynamic work is a minimum and thus probably lead to more iteration per time step. The mathematical model chosen was a 7*5 flat net with 105 degrees of freedom. The 7*5 net was also built as an experimental model and tested in order to verify the static and dynamic nonlinear theories given in this renovation of explicit analysis. The model, of which a diagram is given in Figure 4 and a general view in Figure 5, consisted of a 7*5 cable net, with the cables at 500 mm intervals, in which the cable was 15.24 mm diameter. At the points of intersection the cables were clamped together with thin wires. The cable net was contained within a 4 m by 3 m rectangular steel frame made.

Each steel cable was initially tensioned to around 1 kN and then left for two weeks to permit the individual wires in the strands to bed in. the cables were readjusted to 11.5 kN. This tension was maintained and checked at intervals throughout the test programme. The “wedge and barrel” was used on hollow cylindrical steel to provide Endcaster degree of freedom to boundary condition of
The erected rectangular net had the specifications shown in Table 1. The values in Table 1 for tensile strength and Young’s modulus were obtained after testing in laboratory.

The mass density influence the stability limit, under some circumstance scaling the mass density can potentially increase the efficiency of an analysis and the explicit dynamic uses a central difference rule to integrate...

the equation of motion explicitly through time. The deflections due to concentrated load on Joint 18 are shown in Figure 7.

Degrees of symmetry about the major, minor axes are investigated by deflections due to concentrated load on Node 18 as shown in Table 2. The investigation consisted of checking the degree of symmetric behavior about the major and minor axes. The degree of symmetric behavior about the minor axis was similarly studied by loading first Joint 16 and then Joint 20.

The results indicate that the percentage difference between the theoretical and experimental displacements decreases with increasing loading. For the maximum loading at 18 joint the percentage differences between the theoretical and experimental displacements at the joints measured ranged between 2.1 and 5.3%. Figure 8 shows the relationship between loads and deflection about the major axis. When the concentrated load is placed on Node 20, the deflection gradually increased from 5.35 E-3 units of deflection on Node 15 until it
Figure 7. Deflections due to concentrated load on Joint 18.

Figure 8. Degree of symmetric about major axis when the load is placed on Nodes 16 and 20.
reached a peak of 1.27E-1 on Node 20. From this point onwards, it is projected to drop sharply until it reached 6.07E-2 on Node 15. When concentrated load is placed on Node 16, the deflection from about 6.07E-2 units on Node 15 rapidly rose to reach a peak of 1.27E-01 on Node 16. From this point onwards, it is projected to fall slightly until it reached 5.35E-3 units on Node 21.

The damping matrix for the proposed theory is calculated separately and its calculation does not affect the formulation of the theory in present form. The energy lost in vibration is due to work done by forces resisting the motion. A general orthogonal damping matrix can be shown to be of the form

$$C = M \sum_n a_n \left( M^{-1} k \right) = \sum_n C_n$$

(28)

$$\varepsilon_n = \sum \frac{1}{2} \omega_n a_k \omega_n a_k$$

(29)

where $\varepsilon_n$ = the damping ratio for mode n, and

$\omega_n$ = the frequency of mode n.

Rayleigh damping which is given by

$$C = a_0 M + a_1 K$$

(30)

and in which $a_0$ and $a_1$ are arbitrary proportionality factors, as contained in Equation (30) and satisfies the orthogonality conditions with regard to both the mass and stiffness. The use of value Rayleigh damping assumes that the damping ratios in all modes can be expressed by the relationship

$$\varepsilon_n = \frac{1}{2} \left( \frac{a_0}{\omega_n} + a_1 \omega_n \right)$$

(31)

Figure 9 shows that when the concentrated load was placed on Node 18, the deflection soared between Nodes 4 and 18 from 5.08E-2 until 1.79E-1. From this point onwards, it is projected to decline slightly to reach 5.02E-2 on Node 32. Difference of deflection in minor and major axes is synchronization.

A mode shape describes the expected curvature of a surface vibrating at a particular mode. Modes shape 1 and 2 are shown in Figures 10 and 11.

Figure 12 shows that increases in degree of freedom in Trujillo algorithm are slowly and changes in degree of freedom are reasonable.

1. Newton-Raphson method (linear)
2. Newton-Raphson method (nonlinear)
3. Trujillo algorithm method (linear)
4. Trujillo algorithm method (nonlinear)

The percentage differences between the theoretical and numerical testing results did not in any case exceed 10% and this is acceptable. The time increment used in this renovation was being smaller than the stability limit of the central-difference operator. The use a small enough time increment will result in an unstable solution. When the solution becomes unstable, the time history response of solution variable such as displacements will usually...
oscillate with increasing amplitude and also the mass scaling was controlled by time incrimination.

CONCLUSIONS

The object of this work was principally to develop an explicit dynamic analysis theory and verify the theory by numerical and excremental testing.

The proposed method was found to be stable for time steps equal to less or less than half the smallest periodic time of the system. The numerical experimentation and experimental testing c by static and dynamic testing of flat net showed a good agreement between the numerical experimentation results and the theoretically predicted values. The Turjillo method founds that method converged rapidly near the solution.

Finally the comparison of experimental and theoretically predicted values showed that the deflection calculated by the proposed nonlinear method gives
Figure 11. 7*5 flat net, Mode 2.
reasonably accurate results.
