ABOUT JPVB

The Journal of Parasitology and Vector Biology (JPVB) is published monthly (one volume per year) by Academic Journals.

Journal of Parasitology and Vector Biology (JPVB) provides rapid publication (monthly) of articles in all areas of the subject such as Parasitism, Helminthology, Cloning vector, retroviral integration, Genetic markers etc.

Submission of Manuscript

Submit manuscripts as e-mail attachment to the Editorial Office at: jpvb@academicjournals.org. A manuscript number will be mailed to the corresponding author shortly after submission.

For all other correspondence that cannot be sent by e-mail, please contact the editorial office (at jpvb@academicjournals.org).

The Journal of Parasitology and Vector Biology will only accept manuscripts submitted as e-mail attachments.

Please read the Instructions for Authors before submitting your manuscript. The manuscript files should be given the last name of the first author.

Instructions for Author

Electronic submission of manuscripts is strongly encouraged, provided that the text, tables, and figures are included in a single Microsoft Word file (preferably in Arial font).

The cover letter should include the corresponding author's full address and telephone/fax numbers and should be in an e-mail message sent to the Editor, with the file, whose name should begin with the first author's surname, as an attachment.

Article Types
Three types of manuscripts may be submitted:

Regular articles: These should describe new and carefully confirmed findings, and experimental procedures should be given in sufficient detail for others to verify the work. The length of a full paper should be the minimum required to describe and interpret the work clearly.

Short Communications: A Short Communication is suitable for recording the results of complete small investigations or giving details of new models or hypotheses, innovative methods, techniques or apparatus. The style of main sections need not conform to that of full-length papers. Short communications are 2 to 4 printed pages (about 6 to 12 manuscript pages) in length.

Reviews: Submissions of reviews and perspectives covering topics of current interest are welcome and encouraged. Reviews should be concise and no longer than 4-6 printed pages (about 12 to 18 manuscript pages). Reviews are also peer-reviewed.

Review Process
All manuscripts are reviewed by an editor and members of the Editorial Board or qualified outside reviewers. Authors cannot nominate reviewers. Only reviewers randomly selected from our database with specialization in the subject area will be contacted to evaluate the manuscripts. The process will be blind review.

Decisions will be made as rapidly as possible, and the journal strives to return reviewers' comments to authors as fast as possible. The editorial board will re-review manuscripts that are accepted pending revision. It is the goal of the JPVB to publish manuscripts within weeks after submission.

Regular articles
All portions of the manuscript must be typed double-spaced and all pages numbered starting from the title page.

The Title should be a brief phrase describing the contents of the paper. The Title Page should include the authors' full names and affiliations, the name of the corresponding author along with phone, fax and E-mail information. Present addresses of authors should appear as a footnote.

The Abstract should be informative and completely self-explanatory, briefly present the topic, state the scope of the experiments, indicate significant data, and point out major findings and conclusions. The Abstract should be 100 to 200 words in length. Complete sentences, active verbs, and the third person should be used, and the abstract should be written in the past tense. Standard nomenclature should be used and abbreviations should be avoided. No literature should be cited. Following the abstract, about 3 to 10 key words that will provide indexing references should be listed.

A list of non-standard Abbreviations should be added. In general, non-standard abbreviations should be used only when the full term is very long and used often. Each abbreviation should be spelled out and introduced in parentheses the first time it is used in the text. Only recommended SI units should be used. Authors should use the solidus presentation (mg/ml). Standard abbreviations (such as ATP and DNA) need not be defined.

The Introduction should provide a clear statement of the problem, the relevant literature on the subject, and the proposed approach or solution. It should be understandable to colleagues from a broad range of scientific disciplines.

Materials and methods should be complete enough to allow experiments to be reproduced. However, only truly new procedures should be described in detail; previously published procedures should be cited, and important modifications of published procedures should be mentioned briefly. Capitalize trade names and include the manufacturer's name and address. Subheadings should be used. Methods in general use need not be described in detail.
Results should be presented with clarity and precision. The results should be written in the past tense when describing findings in the authors’ experiments. Previously published findings should be written in the present tense. Results should be explained, but largely without referring to the literature. Discussion, speculation and detailed interpretation of data should not be included in the Results but should be put into the Discussion section.

The Discussion should interpret the findings in view of the results obtained in this and in past studies on this topic. State the conclusions in a few sentences at the end of the paper. The Results and Discussion sections can include subheadings, and when appropriate, both sections can be combined.

The Acknowledgments of people, grants, funds, etc. should be brief.

Tables should be kept to a minimum and be designed to be as simple as possible. Tables are to be typed double-spaced throughout, including headings and footnotes. Each table should be on a separate page, numbered consecutively in Arabic numerals and supplied with a heading and a legend. Tables should be self-explanatory without reference to the text. The details of the methods used in the experiments should preferably be described in the legend instead of in the text. The same data should not be presented in both table and graph form or repeated in the text.

Figure legends should be typed in numerical order on a separate sheet. Graphics should be prepared using applications capable of generating high resolution GIF, TIFF, JPEG or Powerpoint before pasting in the Microsoft Word manuscript file. Tables should be prepared in Microsoft Word. Use Arabic numerals to designate figures and upper case letters for their parts (Figure 1). Begin each legend with a title and include sufficient description so that the figure is understandable without reading the text of the manuscript. Information given in legends should not be repeated in the text.

References: In the text, a reference identified by means of an author’s name should be followed by the date of the reference in parentheses. When there are more than two authors, only the first author’s name should be mentioned, followed by ‘et al’. In the event that an author cited has had two or more works published during the same year, the reference, both in the text and in the reference list, should be identified by a lower case letter like ‘a’ and ‘b’ after the date to distinguish the works.

Examples:
Abayomi (2000), Agindotan et al. (2003), (Kelebeni, 1983), (Usman and Smith, 1992), (Chege, 1998; 1987a,b; Tijani, 1993,1995), (Kumasi et al., 2001)

References should be listed at the end of the paper in alphabetical order. Articles in preparation or articles submitted for publication, unpublished observations, personal communications, etc. should not be included in the reference list but should only be mentioned in the article text (e.g., A. Kingori, University of Nairobi, Kenya, personal communication). Journal names are abbreviated according to Chemical Abstracts. Authors are fully responsible for the accuracy of the references.

Examples:

Short Communications

Short Communications are limited to a maximum of two figures and one table. They should present a complete study that is more limited in scope than is found in full-length papers. The items of manuscript preparation listed above apply to Short Communications with the following differences: (1) Abstracts are limited to 100 words; (2) instead of a separate Materials and Methods section, experimental procedures may be incorporated into Figure Legends and Table footnotes; (3) Results and Discussion should be combined into a single section.

Proofs and Reprints: Electronic proofs will be sent (e-mail attachment) to the corresponding author as a PDF file. Page proofs are considered to be the final version of the manuscript. With the exception of typographical or minor clerical errors, no changes will be made in the manuscript at the proof stage.
**Fees and Charges:** Authors are required to pay a $550 handling fee. Publication of an article in the Journal of Parasitology and Vector Biology is not contingent upon the author's ability to pay the charges. Neither is acceptance to pay the handling fee a guarantee that the paper will be accepted for publication. Authors may still request (in advance) that the editorial office waive some of the handling fee under special circumstances.

**Copyright:** © 2012, Academic Journals. All rights Reserved. In accessing this journal, you agree that you will access the contents for your own personal use but not for any commercial use. Any use and or copies of this Journal in whole or in part must include the customary bibliographic citation, including author attribution, date and article title.

Submission of a manuscript implies: that the work described has not been published before (except in the form of an abstract or as part of a published lecture, or thesis) that it is not under consideration for publication elsewhere; that if and when the manuscript is accepted for publication, the authors agree to automatic transfer of the copyright to the publisher.

**Disclaimer of Warranties**

In no event shall Academic Journals be liable for any special, incidental, indirect, or consequential damages of any kind arising out of or in connection with the use of the articles or other material derived from the JPVB, whether or not advised of the possibility of damage, and on any theory of liability. This publication is provided "as is" without warranty of any kind, either expressed or implied, including, but not limited to, the implied warranties of merchantability, fitness for a particular purpose, or non-infringement. Descriptions of, or references to, products or publications does not imply endorsement of that product or publication. While every effort is made by Academic Journals to see that no inaccurate or misleading data, opinion or statements appear in this publication, they wish to make it clear that the data and opinions appearing in the articles and advertisements herein are the responsibility of the contributor or advertiser concerned. Academic Journals makes no warranty of any kind, either express or implied, regarding the quality, accuracy, availability, or validity of the data or information in this publication or of any other publication to which it may be linked.

Accepted 15 February 2013

An *in vivo* test was undertaken in order to evaluate the efficacy of an aqueous extract of leaves of *Chenopodium ambrosioides* against nematode parasites in goats. The study used fifteen naturally infected West African Long Legged goats (*Capra hircus*) from Northern Benin. Three levels (1, 2 or 4 ml/kg body weight/3 days treatment) of concentration of the herbal drug were administrated to three experimental groups and in comparison with two control groups (one without treatment and the other treated with levamisole as a reference drug). Results showed significant (P<0.001) decrease of faecal strongyle eggs in experimental groups. After three days of treatment, the reduction in the rate of egg shedding was over 70% in animals treated with herbal medicine, whereas egg shedding rates remained the same in the non treated group. The rates of reduction in faecal eggs reached almost 100% in few days (5 to 6 days) among treated animals without a significant dose-dependent effect. Moreover, helminthological autopsy performed on the study animals after treatment showed an almost total absence of worms. *C. ambrosioides* aqueous extract exerted a kind of parasite clearing effect in the abomasums and in the small intestine. This indicates the effectiveness of the herbal extract against gastrointestinal parasitic. The lowest dosage of 1 ml/kg body weight for three days treatment was found to be appropriate and prescriptive. No acute toxicity was recorded and the autopsy of internal organs revealed only rare cases of congestion and petechiae on the liver and lungs in animals treated with 4 ml/kg body weight.

Key words: Goats, gastrointestinal nematodes, controlling, herbal medicine, *Chenopodium ambrosioides*.

INTRODUCTION

In tropical regions, gastrointestinal parasites are an important impediment for livestock production. Their control is also a real economic constraint since the drugs used to control parasites infection can be costly. Benzimidazoles, avermectins, imidothiazoles and pyrimidines are the main and common anthelmintic moleculars used to protect small ruminants, but most of them are subject to drug resistance (Chandrawanthani, 2004; Gaskin, 2006). Due to these issues, numerous farmers in poor areas are using endogenous recipes. In recent years, there has been a resurgence of interest in herbal medicine. In Africa, many farmers use plants to control animal diseases (Djoueche et al., 2011); thus, African flora may provide pharmaceuticals that are currently unknown to the scientific community and that may be cheaper and more environmentally sound. A dynamic of rationalization of endogenous practices is underway and the medicinal properties of many tropical...

Figure 1. Morning faeces recovery device (diaper) from animals.

plants are being checked. This study aims at evaluating the efficacy of an aqueous extract of the leaves of Chenopodium ambrosioides against strongyle infection in West African Long Legged (WALL) goats. The plant is common in many parts of the world like Europe, Asia and Africa. It is used as medicinal herb (Quinlan et al., 2002; Ruffa et al., 2002; Efferth et al., 2002; MacDonald et al., 2004; Patrício et al., 2008). It is well known in rural areas of Benin as “trouzouman” (in “fongbé”, a national language) where it is deemed effective against some human parasitic diseases such as pinworms, tapeworms, roundworms and hookworms.

MATERIALS AND METHODS

Experimental design

The subjects of this study were 15 over one year old Sahelian goats naturally infested with strongyles (Haemonchus contortus and Trichostrongylus species). These study animals were selected among thirty animals purchased at Zongo livestock market in Cotonou after testing their stools. Only the animals with a faecal eggs count (FEC) over 1000 eggs/g of faeces were used in the study. The subjects were divided into five homogeneous groups (based on body weight and future treatment) of three animals (Table 1).

The plant material consisted of powdered leaves of C. ambrosioides. The leaves were harvested in December 2011 at Hévié, district of Abomey-Calavi, Department of Atlantic, Benin, where the plant grows naturally. These leaves were sun-dried, then ground, bottled and kept dry within the Applied Biology Research Laboratory (LARBA) of the Abomey-Calavi Polytechnic School. Two substances were used as drugs in the study: the herbal drug and the control drug. The herbal drug was the aqueous extract of the powder of C. ambrosioides. It was obtained by infusing, during 30 min, 50 mg of powder in 1000 ml of distilled and deionised hot water. The filtrate was used as the herbal drug at the latest 24 h after. Levamisole bolus® (a conventional anthelmintic) was used as a control drug.

In vivo test of the anthelmintic activities of the drugs

The in vivo anthelmintic activity of the leaves of C. ambrosioides was assessed in farm conditions. For 15 days of adaptation, the animals were fed ad libitum with forage and received daily 1000 g of concentrate. The experiment was undertaken from December 2011 to January 2012 at the Doguici farm, located at Attagon, district of Allada. The parasitological status of the animals was reconfirmed according to the selecting criteria (FEC ≥ 1000) first. From the beginning of the test (day 0) to the third day (day two), animals received the appropriate treatment (Table 1) and their general conditions and behaviour were carefully monitored by the booking of animal’s posture, temperature, respiratory frequency, ruminations, aspect and frequency of faeces; any toxicological abnormality. Each night of the experiment, each study animal was outfitted with a diaper-like collection sheet (Figure 1) in order to recover, individually and efficiently, the morning faeces of the animals. Faecal material was collected daily for each animal and was stored at 4°C in sealed labelled vials. A total of 150 samples were then taken and examined for faecal eggs counts. The parasitological examination method of Mc Master (Gaskin, 2006) was used to assess the FEC over 10 days (three adaptation days and seven experiment days). The herbal medicine’s efficacy was evaluated by calculating the reduction rates of faecal eggs shedding (R_{FES}) with the following formula.

\[ R_{FES} (n) = 100 \times \frac{(FEC_0 - FEC_n)}{FEC_0} \]

where \( R_{FES} \) = faecal eggs shedding rate of day “n”, \( FEC_n \) = faecal eggs count of day “n” and \( FEC_0 \) = faecal eggs count before treatment.
**Helminthological and toxicological autopsy**

At the end of the experiment (day 10), the animals were slaughtered at the abattoir of Cotonou. Their digestive systems were collected and examined tracking lesions and present adult nematodes or cestodes worms. The abomasums and intestines of each gut are separately and carefully inspected after being incised along their long axis. The luminal content was recovered in a container for examination. The mucosa was also inspected for fixed worms. Worms were then collected in glass bottles containing 70% ethanol for nematodes and 5% formalin for other helminthes and were transferred to the LARBA. Identification of parasites was done later based on criteria provided by Zajac et al. (2006). The worm burden for each animal was determined for each species of parasite.

**Statistical analysis**

The FEC recorded data and the calculated eggs shedding reduction rates ($R_{\text{FES}}$) were performed under Stata 11 following a Poisson distribution model.

**RESULT AND DISCUSSION**

**In vivo anthelmintic effects of *C. ambrosioides* aqueous extract**

The daily reduction (percent) of faecal eggs excreted in each treatment condition is as shown in Figure 2. There was a significant decrease in eggs excreted with all treatment when compared with the control group ($P<0.001$). Reduction of faecal eggs excretion (increase of $R_{\text{FES}}$) was seen spontaneously (72 h) at levels over 70% (required level for biological significance according to Githiori et al., 2003) in the experimental groups ($E_{G_{1}}$ ml/kg, $E_{G_{2}}$ ml/kg and $E_{G_{4}}$ ml/kg). Reduction in rates approached 100% by the sixth day in the $E_{G_{4}}$ ml/kg group. No significant difference was found between the results for the $E_{G_{4}}$ ml/kg and CGlev groups. With reference to the results of similar tests with other herbal plants, *C. ambrosioides* can be considered very efficient in decreasing the excretion of faecal parasites eggs. For example, roots’ extracts of *Halothamus somalensis* have induced only 50% reduction within three weeks (Dawo and Tibbo, 2005). A high $R_{\text{FES}}$ of 96.2% was recorded in sheep as maximum with a four plants formulation (Zaman et al., 2012) within two weeks. The efficacy of *C. ambrosioides* was not dose-dependent like several other cases of herbal medicines since the levels of success were not significantly different between the dosages. This means that the lower concentration could be a suitable and prescriptive one.

**Acute clinical toxicity**

Only the presence of pasty stools indicated a perturbation of the digestive transit in animals treated with the two highest doses of extract.

**Autopsy results**

At helminthological autopsy, the parasites burden in the animals was near zero with treated animals while the untreated group harboured more than 350 adult of the main gastrointestinal nematodes (*H. contortus, Trichostrongylus*...
spp, and *Trichurus* spp). The herbal extract had a potent deworming effect similar to that seen with levamisole.

The intestinal mucosa, the lung and liver’s parenchyma showed a few petechial lesions (Figure 3) with animals treated with 4 ml/kg body weight dosage. This implies a dose-related toxicity, but no immediate distress or life-threatening effects were observed. These results confirm however the toxicological risks of the plants. Therefore, using a minimum dosage must be recommended.

**Conclusion**

This study shows that an aqueous extract of the leaves of *C. ambrosioides* is a potent anthelmintic in WALL goats. Ease of formulation and the efficacy of low dose promote its use in farmers as an alternative to synthetic molecules. Further studies are needed to clarify the active ingredients and the mode of action as well as long term dosage utilization.

**ACKNOWLEDGEMENTS**

The study was made possible through the support of the NGO Doguici who put provided access to their unit of livestock production facilities. They authors thank the villagers in Kpoguetomey, Attogon, District of Allada for their cooperation. This study is dedicated to the memory of the Late Mother Anne-Marie KPOGUE, a resident of the village and resource person who actively contributed to the monitoring of the study animals.

Prevalence and intensity of nodular oesophagostomosis in West African Long Legged goats in Northern Benin

Sahidou Salifou¹, Dadjo Florian Daga² and Sabbas Attindehou¹*

¹Laboratory of Applied Biology Research, University of Abomey-Calavi, 01 BP 2009 Cotonou, Benin.
²Department of Animal Production, Faculty of Agricultural Sciences, University of Abomey, 01 BP 526 Cotonou, Benin.

Accepted 28 January, 2013

This study was conducted between January and December, 2011 to assess the prevalence and intensity of nodular lesions caused by Oesophagostomum species into the intestine of Benin goats. Intestines of 384 West African Long Legged (WALL) goats, from Northern Benin, were examined during slaughter, and 241 intestines (62.8%) were found to be positive for nodular lesions. The infection rate was significantly (p < 0.05) higher during the rainy season in comparison with dry season. Animals above one year of ages were mostly affected (82.5%). Extensive lesions were observed in 95 large intestines (24.9%) and calcified nodules were observed in 130 intestines (34%).

Key words: Oesophagostomum species, nodules, goats, prevalence, Northern Benin.

INTRODUCTION

The climatic conditions of tropical Africa are conducive for development of parasites, notably the exogenous stage of their life cycle. Therefore, helminthosis is an absolute and important constraint in livestock production in Tropical Africa. The prevalence of gastrointestinal strongyles and their impact on yields are described by many authors (Sykes, 1994; Mortensen et al., 2003) and several reports are also available regarding haemonchosis, most detrimental of which is strongylosis which is synonymous to small ruminants production in Sub-Saharan Africa (Ouattara and Dorchies, 2001; Achi et al., 2003; Osakwe and Anyigor, 2007; Attindehou et al., 2012). However, information is available regarding other pathogens like Oesophagostomum, which also causes important economic losses (Olivares et al., 2001) by decreasing animal productivity and market value of the viscera due to the presence of nodules in the intestines. The assessment of nodular oesophagostomosis importance in Benin is very timely and relevant, especially in the Northern region where farming is a major activity. This study aimed to determine the prevalence and intensity of nodules due to Oesophagostomum spp. in West African Long legged Goats in Benin.

MATERIALS AND METHODS

Period and study area

The study was undertaken between January and December, 2011 in the region located between latitudes 9.5° and 12.5° North and longitudes 1° and 4° West, covering four agro-ecological zones of Northern Benin. During the study period, rainfall was 921.5 mm and temperature varied between 16.2 and 40.6°C. Wet season was from May to November.

Animal

A total of 384 West African Long-Legged (WALL) goats (196 female and 188 males) were selected randomly for the study. On average, 30 animals were screened each month.

Parasitological examination

The parasitological examination consisting of usual slaughterhouse

*Significant variation factor.

Inspection has been used to assess the prevalence and the intensity of nodular lesions in animals. After slaughter, the intestines were isolated, emptied and washed with pressured tap water injection. The external and internal mucosa of both intestines was inspected carefully in search of nodules. Some nodules were incised with a knife in order to characterize the nature (calcified or not calcified). Nodular lesions affecting more than 50% of the length of the small intestine or large intestine were called generalized and considered as a result of heavy infection. When nodules affect less than 25% of the tract, the infection was declared localized. The other cases are referred to as fairly extensive lesions. A logistic regression was performed in Stata 11 (Nicoletti, 2011) to analyze and evaluate age, sex and season influence upon the prevalence and intensity of nodular lesions.

RESULTS

Prevalence of nodular oesophagostomosis and variation factors

Out of 384 examined animals, 241 (62.8%) were positive to nodular oesophagostomosis. Figure 1 shows the infection rates recorded monthly. It highlights the endemic nature of the parasitosis whereas Table 1 clearly shows a higher prevalence in the wet season (p < 0.05). Animals aged one and older were significantly (p < 0.001) more infested than younger ones. No influence of the animal sex could be proven.

Location and intensity of nodular lesions

Parasitic nodules due to Oesophagostomum spp. were found on the terminal portion of the abomasum, on the small intestine and on the large intestine. The mucosa of the large intestine was the most dominant location of nodules (Figure 2). Respectively, 17.8, 25.7, and 56.4% of infected viscera had generalized, fairly extensive and localized lesions.

Figure 1. Nodular oesophagostomosis prevalence.

---

**Figure 2.** Nodular lesions localisation (Frequency of infection; %).
DISCUSSION

The prevalence of nodular oesophagostomosis was important (almost 63%) even if lower values have been recorded in neighboring regions. This is the case in Northern Nigeria where Nwosu et al. (2011) reported a prevalence of 71% in a slaughterhouse investigation. This difference is probably due to the fact that slaughterhouses surveys are likely to overestimate pathology’s prevalence. Indeed, the candidates for the slaughter often look bad, health wise. However, it is clear that oesophagostomosis is an important strongylosis in West African Long Legged goats in West Africa.

*O. columbianum* have been reported in 88.3% of goats in the Central Plateau of Burkina (Belem et al., 2005). The nodular oesophagostomosis was reported in 62% of goats in the Middle Guinea by Barry et al. (2002). Contrary to this, a low rate of 43% was reported by Achi et al. (2003) in savannah region in north of Ivory Coast. The results of the study revealed a fairly clear seasonal variation, with high levels of infection during wet, which was consistent with the observations of Nwosu et al. (2011) but somewhat contradicted the results recorded in Burkina Faso and Ivory Coast (Belem et al., 2005; Achi et al., 2003). A highly significant effect of the age was observed. The elderly were most affected. This is understandable considering the chronicity of nodules, especially in the calcification phase. The intensity of the lesions has been similar to reported findings (Kulo and Seme, 2007; Nwosu et al., 2011).

Conclusion

Nodular oesophagostomosis must be considered as the second main strongyle of high sanitary importance for livestock in Northern Benin after *Haemonchus contortus*. The control of this *Oesophagostomum* spp is very necessary and need to be conducted based on climatic calendar, in association with haemonchosis management.

ACKNOWLEDGEMENTS

The study was funded by Association Doguici NGO through its West African Zoopole Program and with the support of Benin Ministry of High Education and Scientific Research. The authors express their gratitude to these partners.
