ABOUT JPP

The Journal of Pharmacognosy and Phytotherapy (JPP) is published monthly (one volume per year) by Academic Journals.

The Journal of Pharmacognosy and Phytotherapy (JPP) is an open access journal that provides rapid publication (monthly) of articles in all areas of the subject such as ethnobotany, phytochemistry, ethnopharmacology, zoopharmacognosy, medical anthropology etc.

The Journal welcomes the submission of manuscripts that meet the general criteria of significance and scientific excellence. Papers will be published shortly after acceptance. All articles published in JPP are peer-reviewed.

Submission of Manuscript

Submit manuscripts as e-mail attachment to the Editorial Office at: jpp@academicjournals.org. A manuscript number will be mailed to the corresponding author shortly after submission.

The Journal of Pharmacognosy and Phytotherapy (JPP) will only accept manuscripts submitted as e-mail attachments.

Please read the Instructions for Authors before submitting your manuscript. The manuscript files should be given the last name of the first author.

Electronic submission of manuscripts is strongly encouraged, provided that the text, tables, and figures are included in a single Microsoft Word file (preferably in Arial font).

The cover letter should include the corresponding author's full address and telephone/fax numbers and should be in an e-mail message sent to the Editor, with the file, whose name should begin with the first author's surname, as an attachment.

Article Types
Three types of manuscripts may be submitted:

Regular articles: These should describe new and carefully confirmed findings, and experimental procedures should be given in sufficient detail for others to verify the work. The length of a full paper should be the minimum required to describe and interpret the work clearly.

Short Communications: A Short Communication is suitable for recording the results of complete small investigations or giving details of new models or hypotheses, innovative methods, techniques or apparatus. The style of main sections need not conform to that of full-length papers. Short communications are 2 to 4 printed pages (about 6 to 12 manuscript pages) in length.

Reviews: Submissions of reviews and perspectives covering topics of current interest are welcome and encouraged. Reviews should be concise and no longer than 4-6 printed pages (about 12 to 18 manuscript pages). Reviews are also peer-reviewed.

Review Process
All manuscripts are reviewed by an editor and members of the Editorial Board or qualified outside reviewers. Authors cannot nominate reviewers. Only reviewers randomly selected from our database with specialization in the subject area will be contacted to evaluate the manuscripts. The process will be blind review. Decisions will be made as rapidly as possible, and the journal strives to return reviewers' comments to authors as fast as possible. The editorial board will re-review manuscripts that are accepted pending revision. It is the goal of the JPP to publish manuscripts within weeks after submission.

Regular articles
All portions of the manuscript must be typed double-spaced and all pages numbered starting from the title page.

The Title should be a brief phrase describing the contents of the paper. The Title Page should include the authors' full names and affiliations, the name of the corresponding author along with phone, fax and E-mail information. Present addresses of authors should appear as a footnote.

The Abstract should be informative and completely self-explanatory, briefly present the topic, state the scope of the experiments, indicate significant data, and point out major findings and conclusions. The Abstract should be 100 to 200 words in length. Complete sentences, active verbs, and the third person should be used, and the abstract should be written in the past tense. Standard nomenclature should be used and abbreviations should be avoided. No literature should be cited. Following the abstract, about 3 to 10 key words that will provide indexing references should be listed.

A list of non-standard Abbreviations should be added. In general, non-standard abbreviations should be used only when the full term is very long and used often. Each abbreviation should be spelled out and introduced in parentheses the first time it is used in the text. Only recommended SI units should be used. Authors should use the solidus presentation (mg/ml). Standard abbreviations (such as ATP and DNA) need not be defined.

The Introduction should provide a clear statement of the problem, the relevant literature on the subject, and the proposed approach or solution. It should be understandable to colleagues from a broad range of scientific disciplines.

Materials and methods should be complete enough to allow experiments to be reproduced. However, only truly new procedures should be described in detail; previously published procedures should be cited, and important modifications of published procedures should be mentioned briefly. Capitalize trade names and include the manufacturer’s name and address. Subheadings should be used. Methods in general use need not be described in detail.
Results should be presented with clarity and precision. The results should be written in the past tense when describing findings in the authors’ experiments. Previously published findings should be written in the present tense. Results should be explained, but largely without referring to the literature. Discussion, speculation and detailed interpretation of data should not be included in the Results but should be put into the Discussion section.

The Discussion should interpret the findings in view of the results obtained in this and in past studies on this topic. State the conclusions in a few sentences at the end of the paper. The Results and Discussion sections can include subheadings, and when appropriate, both sections can be combined.

The Acknowledgments of people, grants, funds, etc should be brief.

Tables should be kept to a minimum and be designed to be as simple as possible. Tables are to be typed double-spaced throughout, including headings and footnotes. Each table should be on a separate page, numbered consecutively in Arabic numerals and supplied with a heading and a legend. Tables should be self-explanatory without reference to the text. The details of the methods used in the experiments should preferably be described in the legend instead of in the text. The same data should not be presented in both table and graph form or repeated in the text.

Figure legends should be typed in numerical order on a separate sheet. Graphics should be prepared using applications capable of generating high resolution GIF, TIFF, JPEG or Powerpoint before pasting in the Microsoft Word manuscript file. Tables should be prepared in Microsoft Word. Use Arabic numerals to designate figures and upper case letters for their parts (Figure 1). Begin each legend with a title and include sufficient description so that the figure is understandable without reading the text of the manuscript. Information given in legends should not be repeated in the text.

References: In the text, a reference identified by means of an author’s name should be followed by the date of the reference in parentheses. When there are more than two authors, only the first author’s name should be mentioned, followed by ‘et al’. In the event that an author cited has had two or more works published during the same year, the reference, both in the text and in the reference list, should be identified by a lower case letter like ‘a’ and ‘b’ after the date to distinguish the works.

Examples:

Cole (2000), Steddy et al. (2003), (Kelebeni, 1983), (Bane and Jake, 1992), (Chege, 1998; Cohen, 1987a,b, Tristan, 1993,1995), (Kumasi et al., 2001)

References should be listed at the end of the paper in alphabetical order. Articles in preparation or articles submitted for publication, unpublished observations, personal communications, etc. should not be included in the reference list but should only be mentioned in the article text (e.g., A. Kingori, University of Nairobi, Kenya, personal communication). Journal names are abbreviated according to Chemical Abstracts. Authors are fully responsible for the accuracy of the references.

Examples:

Short Communications

Short Communications are limited to a maximum of two figures and one table. They should present a complete study that is more limited in scope than is found in full-length papers. The items of manuscript preparation listed above apply to Short Communications with the following differences:

(1) Abstracts are limited to 100 words; (2) instead of a separate Materials and Methods section, experimental procedures may be incorporated into Figure Legends and Table footnotes; (3) Results and Discussion should be combined into a single section.

Proofs and Reprints: Electronic proofs will be sent (e-mail attachment) to the corresponding author as a PDF file. Page proofs are considered to be the final version of the manuscript. With the exception of typographical or minor clerical errors, no changes will be made in the manuscript at the proof stage.
Fees and Charges: Authors are required to pay a $550 handling fee. Publication of an article in the Journal of Pharmacognosy and Phytotherapy (JPP) is not contingent upon the author's ability to pay the charges. Neither is acceptance to pay the handling fee a guarantee that the paper will be accepted for publication. Authors may still request (in advance) that the editorial office waive some of the handling fee under special circumstances.

Copyright: © 2013, Academic Journals.
All rights Reserved. In accessing this journal, you agree that you will access the contents for your own personal use but not for any commercial use. Any use and or copies of this Journal in whole or in part must include the customary bibliographic citation, including author attribution, date and article title.

Submission of a manuscript implies: that the work described has not been published before (except in the form of an abstract or as part of a published lecture, or thesis) that it is not under consideration for publication elsewhere; that if and when the manuscript is accepted for publication, the authors agree to automatic transfer of the copyright to the publisher.

Disclaimer of Warranties

In no event shall Academic Journals be liable for any special, incidental, indirect, or consequential damages of any kind arising out of or in connection with the use of the articles or other material derived from the JPP, whether or not advised of the possibility of damage, and on any theory of liability. This publication is provided "as is" without warranty of any kind, either expressed or implied, including, but not limited to, the implied warranties of merchantability, fitness for a particular purpose, or non-infringement. Descriptions of, or references to, products or publications does not imply endorsement of that product or publication. While every effort is made by Academic Journals to see that no inaccurate or misleading data, opinion or statements appear in this publication, they wish to make it clear that the data and opinions appearing in the articles and advertisements herein are the responsibility of the contributor or advertiser concerned. Academic Journals makes no warranty of any kind, either express or implied, regarding the quality, accuracy, availability, or validity of the data or information in this publication or of any other publication to which it may be linked.

Accepted 10 December, 2013

The aim of this study seeks to investigate the presence of steroids, triterpenes, alkaloids, saponins, tannins, anthraquinones and flavonoids compounds as the possible agent responsible for the medicinal activities of the leaf of the plant Paullinia pinnata and also to carry out phytochemical screening of the dried leaf of the plant, to extract and fractionate the leaf and finally to carry out thin layer chromatography of the different fractions. In the phytochemical investigation of the plant, the powdered leaves was tested positive for steroids, triterpenes, alkaloids, saponins, tannins, anthraquinones and flavonoids. The presence of the constituents was also found to be similar to those reported for most medicinal plants. In East Africa, the leaves are used against snake bites, rabies, mental problems, blindness and eye troubles, together with the roots, against gonorrhoea, paralysis, wounds, threatened abortion, malaria, ancylostomiasis, and to expel placenta. Roots are applied against eczema, as a tonic and as a styptic medicine.

Key words: Paullinia pinnata, phytochemical, chromatography, flavanoids, alkaloids, materials, tests, tannins, extraction, colour, spray, fractionate.

INTRODUCTION

There are a large number of medicinal plants whose scientific importance has not been explored. All over the world, plants have served as the richest source of raw materials for traditional as well as modern medicine, particularly in Africa and Asia (Tsakala et al., 2006). Knowledge acquired by ancient people was transmitted from generation to generation and new knowledge added to it by the next generation. Gradually, a group of people in each generation started specializing in collecting and processing medicinal plants and using them against various diseases even though many of them had not been identified scientifically. Diseases are best controlled through pharmacotherapy. The study of the many chemical constituents contained in plant is very essential because most drugs used as medicines were later synthesized after a careful study of their constituents and structures (Ghani, 1990). The problem however remains that some drugs are scarce, costly and unavailable to the common man, hence a study of the medicinal importance of plants, scientifically and a confirmation of the use of...
these plants towards curing diseases is a possible solution to development of less costly and effective drugs from our local raw materials (Zamble, 2006).

The medicinal and pharmaceutical properties of plants are due to the type of chemical substance they produce and store. These include compounds that are utilized as food by man and other animals and also other compounds that exert physiological effects on them. This second group of chemical substances often referred to as secondary metabolites, give plants their therapeutic properties. The usual term used to refer to these various chemical substances present in plant is "constituents". The constituent which possess pharmacological properties are called 'active constituents'. Phytochemistry is concerned with the chemical study of these plant constituents (Evans, 2002).

The test used in phytochemical screening should be simple, standard and one should be aware of false positive result and hence the need for carrying out confirmatory tests. The chemical constituents that are of medicinal importance are mainly the secondary metabolites, and the examination of the chemical constituents of the plant can only reveal those compounds that have accumulated to some extent at a specific organ of a given plant. The presence or absence of such compounds depends largely on the extent of accumulation, the amount of plant material used and the analytical method employed (Harborne, 1973). There are a large number of medicinal plants whose scientific importance has not been explored. All over the world, plants have served as the richest source of raw materials for traditional as well as modern medicine, the study of the medicinal importance of plants, scientifically and a confirmation of the use of these plants towards curing diseases is a possible solution to development of less costly and effective drugs from our local raw materials. The plants are distributed in Africa including Nigeria (Brako and Zarucchi, 1993).

*Paullinia pinnata* is a climbing shrub, the leaves are compound with winged rachis, inflorescences stand axillary on long stalks, and bearing paired collected tendrils with white flowers. *P. pinnata* grows in evergreen and mixed forests up to an altitude of 1200 m. The plant is a perennial climber with a height of 2.5 to 8.0 m. The fruit is up to 2.5 cm long (Watson and Dalwitz, 2007). It is a stout and strong woody vine that forms mats in forest openings and ascends rocks and trees by means of forked tendrils to access full sunlight. It may reach 10 m of extension and 12 cm or more of stem diameter. The young, green stems are angularly striated; the plant is easily recognized from the leaves that have five serrated leaflets with prominent veins and a winged rachis and petiole. The fruits are red or dark pink when ripe (Watson and Dalwitz, 2007).

The major aim of this study seeks to investigate the presence of compounds as the possible agent responsible for the medicinal activities of the leaf of the plant *P. pinnata* by carrying out the phytochemical screening of the dried leaf of the plant, extract and fractionate the leaf and to carry out thin layer chromatography of the different fractions.

**MATERIALS AND METHODS**

**Collection and preparation of plant material**

In this research, the plant part utilized were the leaves. The plant was collected from Durumi market in Zaria Local Government, Kaduna state. The leaves were identified at the Herbarium Section of the Department Of Biological Sciences, Ahmadu Bello University, Zaria, with voucher number (9000185). The leaves were dried at room temperature for 13 days and when properly dried the leaves were powdered using clean pestle and mortar, and the powdered plant was size reduced with a sieve. The fine powder was then packed in airtight container to avoid the effect of humidity and then stored at room temperature.

**Extraction of the powdered leaf of the plant**

**Maceration**

The powdered leaves (100 g) was weighed and soaked in 350 ml of methanol in a conical flask. The flask containing the leaves was shaken, corked and left to stand for 48 h at room temperature. After 48 h, the mixture was filtered and the extract was collected and concentrated by evaporation to dryness in evaporating dish (Trease and Evans, 1997).

**Fractionation of the methanol extract**

The methanol extract (2 g) was placed at the top of a silica gel (28 g) wet packed in a chromatographic column and eluted with gradient of hexane and ethyl acetate at ratio of 8:2. 20 ml of the elute were collected in small bottles and labeled 1, 2, 3, ...19, successively. The fractions collected were spotted on thin layer chromatography (TLC) plate and developed. The plate was allowed to dry and sprayed with 20% sulphuric acid then heated in an oven at 105°C for 15 min.

**Phytochemical analysis of Paullinia pinnata**

**Identification of sterols and triterpenes**

Three grams of the powdered leaves was placed in a test tube and 10 ml of 50% alcohol was added, the tube was then placed on a water bath and heated for 3 min. It was then allowed to cool to room temperature and filtered. The filtrate was then evaporated in an evaporating dish to dryness and 5 ml of petroleum ether was added to the dish and stirred for 5 min, the petroleum ether portion was then decanted and discarded. 10 ml of chloroform was then added and stirred for about 5 min, it was then transferred into test tube and 0.5 mg of anhydrous sodium sulphate was added and shaken gently and filtered, the filtrate was then divided into two test tubes and used for the following tests.
Lieberman-Burchard’s reaction: To test tube I, equal volume of acetic anhydride was added and gently mixed. Then 1 ml of concentrated H₂SO₄ was added down the side of the tube. The appearance of a brownish-red ring at the contact zone of the two liquids and a greenish colour in the separation layer indicates the presence of sterols and triterpenes.

Salwoski’s test: To test tube II, 2 to 3 drops of concentrated sulphuric acid was added to form a lower layer. Reddish-brown colour at the inter phase indicates the presence of steroidal ring.

Identification of alkaloids

The powdered leaves (2 g) were boiled in a water bath with 20 ml of 5% sulphuric acid in 50% ethanol. The mixture was cooled and filtered. A portion was reserved. Another portion of the filtrate was put in 100 ml of separating funnel and the solution was made alkaline by adding two drops of concentrated ammonia solution. Equal volume of chloroform was added and shaken gently to allow the layer to separate. The lower chloroform layer was run off into a second separating funnel. The ammoniacal layer was reserved. The chloroform layer was extracted with two quantities each of 5 ml of dilute sulphuric acid. The various extracts were then used for the following test:

Mayer’s test: To the filtrate in test tube I, 1 ml of mayer’s reagent was added drop by drop. Formation of a greenish coloured or cream precipitate indicates the presence of alkaloids (Evans, 2002).

Dragendoff’s test: To the filtrate in test tube II, 1 ml of dragendoff’s reagent was added drop by drop. Formation of a reddish-brown precipitate indicates the presence of alkaloids (Evans, 2002).

Wagner’s test: To the filtrate in tube III, 1 ml of wagner’s reagent was added drop by drop. Formation of a reddish-brown precipitate indicates the presence of alkaloids (Evans, 2002).

Identification of tannins

Two grams of the leaves was extracted with 10 ml of 50% alcohol, it was then filtered and the filtrate was divided into three portions for the following tests.

Ferric chloride test: Three drops of diluted solution of FeCl₃ was added to the test tube I, production of a blue or greenish-black colour that changes to olive green as more ferric chloride is added indicates the presence of tannins (Evans, 2002).

Bromine water test: Three drops of bromine water was added to the second portion of the filtrate. A buff coloured precipitate indicates condensed tannins while hydrolysable tannins gave none (Evans, 2002).

Lead sub-acetate test: Three drops of lead sub acetate solution was added to the third portion. Occurrence of a coloured precipitate indicates the presence of tannins (Evans, 2002).

Identification of anthraquinones

Borntrager’s test (for free anthracene derivatives): The powdered leaves (0.5 g) was taken in a test tube and 5 ml of chloroform was added and shaken for 5 min. The mixture was filtered and the filtrate shaken with equal volume of 10% ammonia solution. A pink, red or violet colour in the aqueous layer after shaken indicates the presence of free anthraquinone (Evans, 2002).

Modified Borntrager’s test (for combined anthracene derivatives): One gram of the powdered leaves was boiled with 5 ml of 10% hydrochloric acid for 3 min. The hot solution was filtered in a test tube, cooled and extracted gently with 5 ml of benzene. The upper benzene layer was pipetted off and shaken gently in a test tube with half of its volume of 10% ammonium hydroxide solution. A rose pink to cherry red colour in the ammonia layer indicates the presence of anthraquinone (Evans, 2002).

Identification of saponins

Frothing test: The powdered leaves (0.5 g) was placed in a test tube and 10 ml of distilled water was added and shaken vigorously for 30 s. It was then allowed to stand for 30 min and observed. Formation of honey comb froth indicates the presence of saponins (Satowora, 1993).

Haemolysis test: One gram of the leaves was extracted with distilled water and 2 ml of aqueous NaCl solution was placed in a test tube and 2 ml of the filtrate was added to the test tube. Then 3 drops of an animal blood was added to the tube by means of a syringe and mixed gently by inverting the tube (no shaking) and allowed to stand for 15 min. The settling down of the red blood cells denotes the presence of saponins.

Identification of flavonoids

Two gram of the powdered leaves sample was completely detanned with acetone. The residue was extracted with warm water after evaporating the acetone on a water bath. The mixture was then filtered while hot, the filtrate was allowed to cool and used for the following test:

Shinoda’s test: Few magnesium chips were added to 3 ml of the aqueous solution and 2 drops of dilute hydrochloric acid was added and warmed. A pink or red colour indicates the presence of flavonoids (Evans, 2002).

Sodium hydroxide test: To test tube II, 2 mls of 10% NaOH solution was added, yellow solution indicates the presence of flavonoids which on adding dilute hydrochloric acid becomes colourless (Evans, 2002).

FeCl₃ test: To test tube III, 3 drops of FeCl₃ solution was added, production of greenish-black colour indicates the presence of phenolic nucleus (Sofowora, 1993).

Thin layer chromatography

Parameters used

Absorbent (silica gel) Merck, Germany 120 mesh size, eluting solvent- n-hexane: ethyl acetate (8:2); technique: ascending; visualization aids: day light, methanol-sulphuric acid and heated at 105°C for 15 min.
**Development of thin layer chromatography for the extract**

The extract was applied onto the plate about 1.5 cm above the edge and 0.5 cm away from the margin, when the spot was dried, the plate was observed and then sprayed with methanol-sulphuric acid and then heated in oven at 105°C for 15 min. The solvent used for the mobile phase was n-hexane and ethyl acetate (8:2).

**Column chromatography of the extract**

The methanolic extract of the powdered leaf was added into a column pre-packed with silica gel. It was then run using n-hexane/ethyl acetate (8:2) and the separated fractions were collected separately in bottles.

**TLC of the fractions**

Using capillary tubes, the various fractions collected from column chromatography were spotted on a silica gel pre-coated plate 1.5 cm from the base and 0.5 cm away from the edge. Each plate was allowed to dry before putting it in a chromatographic tank containing specific solvent system. The developed plate was sprayed using methanol sulphuric acid.

**RESULTS**

The followings are the results of analysis of phytochemical constituents in *P. pinnata* leaf.

**Identification of sterols and triterpenes**

**Lieberman-burchard’s test**

A violet ring was formed at the contact zone of the two liquids; the upper layer becomes green which indicates the presence of sterols.

**Salwoski’s test**

A reddish brown colour was observed at the interphase which indicates the presence steroid ring.

**Identification of tannins**

**Ferric chloride test**

A greenish precipitate was formed which indicates the presence of condensed tannins.

**Lead sub-acetate test**

A coloured precipitate was observed indicating the presence of tannins.

**Bromine water test**

A buff colour precipitate was observed which indicates the presence of tannins.

**Identification of alkaloids**

**Mayer’s test**

A cream (buff) coloured precipitate was formed which indicates the presence of alkaloids.

**Dragendoff’s test**

A reddish-brown precipitate was formed which indicates the presence of alkaloids.

**Wagner’s test**

A reddish-brown precipitate was formed which indicates the presence of alkaloids.

**Identification of flavonoids**

**Ferric chloride test**

A greenish-black colour was observed which indicates the presence of flavonoids.

**NaOH test**

A yellow coloured solution was formed which indicate the presence of flavonoids.

**Shinoda’s test**

A pinkish coloured solution was observed which indicates the presence of flavonoids.

**Identification of saponins**

**Frothing test**

A honey comb froth was formed which persisted for about 10 minutes indicating the presence of saponins.
Table 1. Summary of the chromatographic analysis results for the combined fractions obtained after column chromatography.

**Haemolysis test**

The red blood cell settled down in the test tube which indicates the presence of saponins.

**Identification of anthraquinones**

**Borntrager’s test**

A pink colour solution was formed showing the presence of free anthracene derivative.

**Modified Borntrager’s test**

A pinkish colour was formed in the ammonia layer which indicates the presence of anthraquinone.

**Layer chromatography**

Technique used: Ascending; eluting solvent: n-hexane:ethyl acetate (8:2); visualization aids: Day light, methanol-sulphuric acid and heated at 105°C for 15 min.

(a) Before spray: Number of spot = 3; Colour: Spot 1: Light yellow, Spot 2: Yellow, Spot 3: Green.
(b) After spray: Number of spot = 6; Colour: Spot 1: Light yellow, Spot 2: Yellow, Spot 3: Pink, Spot 4: Green, Spot 5: Violet, Spot 6: Purple.

Retention factor ($R_f$) = Distance moved by the component/Distance moved by the solvent.

Spot 1 $R_f$ value = $1.4/7.2 = 0.19$
Spot 2 $R_f$ value = $4.6/7.2 = 0.64$
Spot 3 $R_f$ value = $5.7/7.2 = 0.79$
Spot 4 $R_f$ value = $6.1/7.2 = 0.85$
Spot 5 $R_f$ value = $6.4/7.2 = 0.89$
Spot 6 $R_f$ value = $6.9/7.2 = 0.96$

**DISCUSSION**

Phytochemical analysis of the leaves of *P. pinnata* was successfully carried out, hexane/ethyl acetate at ratio (8:2) was found to be a good solvent system for the separation of the active constituents of the plant and using TLC, the separation of these constituents on the chromatogram was carried out. The powdered leaf was tested positive for steroids, triterpenes, alkaloids, saponins, tannins, anthraquinones and flavonoids. These results agreed with the literature review on the plant which showed these chemical constituents to be present (Tsakala et al., 2006). The TLC chromatograms of elutes collected showed different spots and colours ranging from fairly coloured to distinctively visible colours after spraying with 20% sulphuric acid indicating the presence of such chemical constituents (Plates 1 to 4 and Table 1).

**Conclusion**

The phytochemical constituents of the leaf of *P. pinnata* was investigated. The leaf was found to constitute...
Plate 1. Chromatogram of methanol extract developed in hexane/ethyl acetate (8:2) before spray.

Plate 2. Chromatogram of methanol extract developed in hexane/ethyl acetate (8:2) after sprayed with 20% sulphuric acid and heated at 105°C for 15 min.

Plate 3. Chromatogram of column fractions in hexane/ethyl acetate before spray.

Plate 4. Chromatogram of column fractions in hexane/ethyl acetate (8:2) after spray with 20% sulphuric acid and heated at 105°C for 15 min.
steroids, triterpenes, alkaloids, saponins, tannins, anthraquinones and flavonoids. The leaf is an African woody vine widely used in traditional medicine for the treatment of malaria and as a remedy against different forms of pains and as a natural cure (Jimoh et al., 2007). The presence of the constituents was also found to be similar to those reported for most medicinal plants. In East Africa, the leaves are used against snake bites, rabies, mental problems, blindness and eye troubles, together with the roots, against gonorrhoea, paralysis, wounds, threatened abortion, malaria, ancylostomiasis, and to expel the placenta. Roots are applied against eczema, as a tonic and as a styptic medicine (Abourashed et al., 1999). The whole plant is applied for bad skin conditions, for wounds and microbial infections. The root decoction is drunk in the case of nausea and vomiting. In Nigeria, the research work is still in the initiation stage and the work was carried out to find its phytochemical constituents in relation to the leaf elsewhere in Africa.

Phytochemical profiling of phytoconstituents of grape, *Jatropha curcas* and Neem (*Azadirachta indica*) extracts

Olabinri B. M.*, Adepoju E. A., Zainab A. A. and Ahmed A. A.

Department of Biochemistry, Ladoke Akintola University of Technology, Ogbomoso, Nigeria.

Accepted 16 December, 2013

This study investigated the phytoconstituents in Neem (seed and flower), *Jatropha curcas* (stem and root bark) and grape (stem bark and leaves) in some selected solvents. Phytochemical screening revealed the presence of bioactive compound saponin in all the parts of the three plants in water extract only. Saponin was absent in other solvents used (ethanol, ethyl acetate, propan-2-ol, methanol, n-butanol and acetone). Ethanol, ethyl acetate and methanol were the most promising solvents to extract flavonoids in both the seed and flower of Neem plant. Acetone and ethanol were the most promising solvents to extract flavonoids in the stem bark of *J. curcas*. In the root bark of *J. curcas*, acetone and ethyl acetate were the most promising solvents to extract flavonoids. In grape (*Citrus paradisi*) leaves, ethanol, water and acetone were the most promising solvents to extract flavonoids. In the stem bark of grape, water, ethyl acetate and acetone proved promising as extraction solvents for flavonoids. All the parts of the plants studied were positive for alkaloid in ethanol and acetone extracts. The seed extract of Neem (*Azadirachta indica*) was strongly positive in ethanol only. Terpenoids were detected in ethyl acetate and n-butanol in all the parts of the three plants. Aged flower extract of Neem plant with pale pink colour could be exploited as a novel source of colourant. Volatile oil was not restricted to *J. curcas* stem and root barks, it was also present in *C. paradisi* stem and root barks. The nutritional significance, economic and toxicological implications of phytoconstituents analysed in the plants were discussed.

Key words: Phytomedicine, bioactive compounds, natural product, drug discovery, preventive medicine.

INTRODUCTION

Plant extracts or secondary metabolites have served as antioxidants in phytotherapeutic medicines to protect against various diseases for centuries (Halliwell, 1996). The grape fruit (*Citrus paradisi*) is a subtropical citrus tree known for its bitter fruit (Sean and Henry, 2003). Grape contains many bioactive constituents such as flavonoids, polyphenols, anthocyanins and stilbene derivatives of resveratrol (Cetin and Sagdic, 2009). Grape fruit mercapatan, a sulphur-containing terpene, is one of the substances which have a strong influence on the taste and odour of grape fruit (Buettner and Schieberle, 1999). Grape is used in the treatment of B and C type viral hepatitis (Block et al., 1994). Grape oil is used in aromatherapy, and its historically known for its aroma (Ann, 1991). The seeds have antioxidant (Yigit et al., 2009) and cardioprotective (Falchi et al., 2006) properties. The grape seed extract displayed reduction of platelet adhesion and aggregation and generation of superoxide radical (Olas et al., 2008).

The utility of *Jatropha curcas* oil and its esters as replace-ment for petrodiesel is well documented (Roach et al., 2012; Kywe and Oo, 2009). The seed oil of the plant is rich in phorboesters (Roach et al., 2012). The antifungal effect of the seeds is due to its phorbol esters

*Corresponding author. E-mail: olabinriexcellent@yahoo.com.
(Saetea and Suntornskul, 2010). The fruit possessed abortifacient property (Goonasekera et al., 1995). The latex and leaf extracts of the J. curcas showed the highest in vitro antioxidant activity and the extracts of different plant parts contained various levels of phenolics, flavonoids and saponins (Oskoueian et al., 2011; Sawant and Joshi, 2010). Saponin isolated from the plant is useful in managing inflammation (Just et al., 1998). The aqueous branch extract of the plant inhibited HIV-1 (Matsuse et al., 1999).

Azadirachta indica (Neem) belongs to the mahogany family (Meliaceae) (Girish and Shankara, 2008). The leaf powder of A. indica is used as a biosorbent for the removal of congo red from water (Bhattacharyya and Sarma, 2003). Tignic acid is responsible for the bitter taste of the seed oil (Lale, 2002). Beta-nimboles, flavonoids and carotenoids are the constituents of the flower of A. indica (Sarithanudomchai et al., 2005). The genotoxic effect of the plant is due to the most active principle (azadirachtin) (Khan and Aswathy, 2003). Neem oil is an indigenous product and a practical solution to curtail mosquito nuisance (Mishra et al., 1995).

The phytochemical screening of the aqueous, ethanolic and methanolic extracts of the J. curcas has been reported (Igbinosa et al., 2009), but the authors failed to categorize the bioactive compounds in the three solvents. The methanolic leaf extract of the plant revealed the presence of bioactive compounds like flavonoids, tannins, alkaloids, saponin, steroids and triterpenoids (Uche and Aprioku, 2008). Sharma et al. (2012) reported the presence of bioactive compounds such as alkaloids, saponins, tannins, terpenoids, steroids, glycosides, phenols and flavonoids in the extracts of root, stem and leaf of the plant in one solvent only (methanol), but failed to utilize several solvents. Daniel et al. (2012) reported the bioactive principles in the leaves, bark and seed extracts of the plant using methanol alone, but failed to use many solvents.

This study was designed to add more knowledge to the bioactive compounds in several solvents (seven solvents), which include water, ethanol, ethyl acetate, n-butanol, propan-2-ol, methanol and acetone.

MATERIALS AND METHODS

Collection of plant

The seeds and flowers of Neem (A. indica) were collected from the premises of Ladoke Akintola University of Technology, Ogbomoso, Nigeria on the 14th of February, 2010. The root and stem barks of J. curcas was collected from Oke-Anu area of Ogbomoso, Nigeria on the 6th March, 2010. The stem bark and leaves of grape fruit plant was collected from the premises of Soun High School, Ikuye, Ogbomoso, North Local Government, Ogbomoso, Nigeria on the 14th March, 2010.

Phytochemical analysis

The phytochemical analysis was carried according to standard methods (Parekh and Chanda, 2006; Trease and Evans, 2002; Sofowora, 1993; Harborne, 1973) with little modification. For qualitative test for alkaloid, Wagner's test was utilized. To 1 ml of extract, 1 ml of 1% HCl was added and the mixture steamed in a water bath. To the solution, 6 drops of Wagner's reagent was added. Formation of brownish precipitate is indicative of alkaloids.

For flavonoid detection, Shibata's test was used, and it involved the addition of 0.4 ml of concentrated HCl to 1 ml of extract, followed by the addition of few pieces of magnesium ribbon. Pink colour indicates the formation of flavonoid. Volatile oil was detected in the extract by the addition of 0.1 ml NaOH solution to 1 ml of extract, followed by small quantity of dilute HCl. A white precipitate indicates the presence of volatile oil. Froth test was employed for the qualitative identification of saponin. To 2 ml extract, 2 ml of distilled water was added and the mixture shaken. Persistent/stable foam was used to detect saponin.

Tannin in the extract was detected by adding few drops of 0.1% FeCl3 to 1 ml extract. Bluish black indicates tannin. For phlobatannin detection, 1 ml of 1% HCl was added to 1 ml extract and the mixture was steamed in a water bath for 10 min. Formation of a red precipitate indicates phlobatannin. For hydrolysable tannin detection, 2 ml of 10% ammonia solution was added to 1 ml extract and formation of emulsion indicates the compound. For steroid identification, 1 ml of acetic anhydride was added to 0.5 ml extract, followed by 2 drops of concentrated H2SO4. Formation of a violet/brown ring at the junction indicates the presence of steroid.

For cardiac glycoside identification, legal test was used. To 1 ml of extract, 0.5 ml of glacial acetic was added, followed by 9 drops of FeCl3 solution, and 0.5 ml of concentration slowly near the side of the test tube. A brown ring at the junction is positive for cardiac glycoside. For cardenolide aglycone, legal test was employed. To 1 ml of extract, 7 drops of pyridine, 7 drops of NaOH solution and 7 drops of sodium nitroprusside were added. Formation of a deep red colour that fades to brown indicates cardenolide aglycone.

RESULTS

Table 1 showed the phytochemical data for flavonoid in different parts of Neem, J. curcas and C. paradisi in solvents of interest. The water extracts of A. indica and J. curcas lacked flavonoid. The leaves and stem bark extracts of C. paradisi showed the presence of flavonoid. All the butanol extracts lacked flavonoids in all the parts of the three plants investigated. Acetone proved most promising in the extraction of flavonoid in all the parts of all the plants except the seed of A. indica.

Saponin was detected only in the water extract of all the parts of the three plants. Other solvents lacked saponin (Table 2).

Ethanol and acetone were the promising solvents for all the parts of the plant investigated (Table 3). Volatile oil was detected in all the parts of C. paradisi, J. curcas and A. indica with water, and butanol as separate extraction solvents. Ethyl acetate and ethanol were suitable solvents except that both solvents failed to detect volatile oil in A. indica flower (Table 4).

Cardenolide aglycone was absent in the water, ethanol, ethyl acetate, propan-2-ol in all the parts investigated (Table 5). It was only present in n-butanol seed extract of A. indica, but absent in other parts. Acetone was the most promising for the detection of the bioactive compound in all parts investigated, except the acetone seed.

Cardiac glycoside was absent in water, ethanol, propan-2-ol and methanol extracts in all the parts investigated (Table 6). Cardiac glycoside was detected in...
the stem and root acetone extract in *J. curcas* and *C. paradisi*.

Tannin was absent in the ethyl acetate, propan-2-ol, methanol and n-butanol extracts of all the parts of the three plants (Table 7). Tannin was positive in ethanolic extracts of the parts of the plants except the ethanolic seed extract of *A. indica*.

Hydrolysable tannin was present in n-butanol and ethyl acetate extracts of the three plants. Phytochemical screening showed the absence of hydrolysable tannin in water, ethanol, propan-2-ol, methanol and acetone extracts (Table 8).

Phytochemical screening revealed that steroid was strongly positive in methanolic flower extract of *A. indica* (Table 9). The aqueous, ethyl acetate, propan-2-ol and acetone extracts in all the parts of the plants lacked steroid.

Terpenoid was positive in ethyl acetate and n-butanol extracts in all the parts of the plants. The aqueous, ethanol, propan-2-ol and methanolic extracts lacked terpenoid in all the parts of the three plants.

Phlobatatin was only positive in methanolic leaf extract of *C. paradisi* (Table 11). Meth indicates methanol, while n-butanol and pro indicate n-butanol and propan-2-ol, respectively. After 20 days of soaking, saponin was present in both the Neem flower and seed extracts. Flavonoid and

tannin were absent in seed and flower extracts of Neem plant after 20 days of soaking (Table 12).

**DISCUSSION**

In this study, phytochemical screening revealed the presence of bioactive compound alkaloid in the stem and root of *J. curcas* in methanol, which is consistent with the finding of Sharma et al. (2012). However, this study failed to detect the presence of flavonoids, saponin and cardiac glycosides, terpenoids and tannin in the methanolic extracts of the root and stem of the plant, while Sharma et al. (2012) detected the presence of the bioactive compounds. Phytochemicals are chemical compounds formed during the plants normal metabolic processes; these chemicals are often referred to as secondary metabolites of which there are several classes including alkaloids, flavonoids, coumarins, glycosides, polysaccharides, phenols, tannins, terpenes and terpenoids (Okwu, 2004).

In this work, flavonoid was detected in the methanolic seed extract of *A. indica*, which is in agreement with the earlier investigation (Daniel et al., 2012). The two bioactive compounds (saponin and tannin) previously identified with methanol as extraction solvent in other laboratory (Daniel et al., 2012) were not detected in the present study. In this study, alkaloid in the methanolic seed extract of *A. indica* was detected, which was not consistent with the work of Daniel et al. (2012). Methanol and ethanol have been proved as effective solvents to extract phenolic compounds (Sidduraju et al., 2003).

Water was a promising solvent for the extraction of bioactive compounds like flavonoids, cardiac glycosides and terpenoids for the leaf of *A. indica* (Selvan et al., 2012), but the same solvent failed to detect these bioactive compounds in *A. indica* flower in this work. Moreover, saponin was detected in the water flower extract of the plant. Saponin had earlier been reported to be present in the water extract of *A. indica* leaf (Selvan et al., 2012).

Saponins are amphipathic glycosides grouped phenomenologically by the soap-like foaming they produce when shaked in aqueous solutions (Hostettmann and Marston, 1995). Most saponins function as antioxidants, because they possess a special moiety (2,3-dihydr-2.5 –dihydroxy6-methyl-4-pyran -4-one) which act by forming hydroperoxide intermediates thus removing free radicals (Hu et al., 2002). Saponins possess haemolytic action on human erythrocytes (Baumann et al., 2000). Saponins with acyl residues or oxide-ring moiety tend to show haemolytic activity (Oda et al., 2000).

Flavonoids are important in human diet and are present in plant extracts that have been used for centuries in oriental medicine (Di Carlo et al., 1999). Antioxidant properties, reactive oxygen species scavenging, and cell function modulation of flavonoids could account for the large part of their pharmacological activity (Limasset et al., 1993).

Raw oil of *J. curcas* has been used as a substitute for petrol-diesel both in modified and unmodified diesel engines (Jingura et al., 2010). *J. curcas* plant found in Nigeria has the potential of boosting the economy in term of biodiesel production (Belewut et al., 2010). n-Hexane may be preferable in the extraction of biodiesel oil from *J. curcas* (Belewut et al., 2010), although petroleum ether had been used with lower yield (Adebayo et al., 2011).

Some alkaloids are known to precipitate hepatocyte necrosis and cytoskeleton disorganization (Lekhehal et al., 1996). Phenolic alkaloids such as caffeic acid phenyl ester (CAPE) have been reported to possess beneficial effects such as anti-tumor property against human breast cancer line (Grunberger et al., 1988) and in the treatment of acute inflammation (Orban et al., 2000).

Cardiac glycosides are class of natural product, which are used to increase the cardiac contractile force in patients with congestive heart failure and cardiac arrhythmias (Hauptman et al., 1999).

In this work, the water flower extract of *A. indica* afforded pale colour after 20 days of soaking in water. The water flower extract of the plant could be exploited as a colourant, although with caution. The aqueous flower extract with pale colour was positive for saponin. This requires future research. This could be due to browning process. The enzymatic oxidation of polyphenols, particularly, flavonoids, occurs during storage when cell integrity is affected (Cheynier, 2005, 1994). Flavonoids, particularly, ortho-diphenols, can be oxidized to their corresponding semiquinones and quinones by oxidases such as polyphenol oxidase and peroxidases (Yoruk and Marshall, 2003; Walker and Ferrar, 1998).
