ABOUT JMA

The *Journal of Microbiology and Antimicrobials (JMA)* (ISSN 2141-2308) is published monthly (one volume per year) by Academic Journals.

*Journal of Microbiology and Antimicrobials (JMA)*, is an open access journal that provides rapid publication (monthly) of articles in all areas of the subject such as Disorders of the immune system, vaccines and antimicrobial drugs, Microbial Metabolism, Protozoology etc.

The Journal welcomes the submission of manuscripts that meet the general criteria of significance and scientific excellence. Papers will be published shortly after acceptance. All articles published in JMA are peer-reviewed.

Submission of Manuscript

Please read the *Instructions for Authors* before submitting your manuscript. The manuscript files should be given the last name of the first author

Click here to Submit manuscripts online

If you have any difficulty using the online submission system, kindly submit via this email jma@academicjournals.org.

With questions or concerns, please contact the Editorial Office at jma@academicjournals.org.

Instructions for Author

Electronic submission of manuscripts is strongly encouraged, provided that the text, tables, and figures are included in a single Microsoft Word file (preferably in Arial font).

The cover letter should include the corresponding author's full address and telephone/fax numbers and should be in an e-mail message sent to the Editor, with the file, whose name should begin with the first author's surname, as an attachment.

Article Types
Three types of manuscripts may be submitted:

Regular articles: These should describe new and carefully confirmed findings, and experimental procedures should be given in sufficient detail for others to verify the work. The length of a full paper should be the minimum required to describe and interpret the work clearly.

Short Communications: A Short Communication is suitable for recording the results of complete small investigations or giving details of new models or hypotheses, innovative methods, techniques or apparatus. The style of main sections need not conform to that of full-length papers. Short communications are 2 to 4 printed pages (about 6 to 12 manuscript pages) in length.

Reviews: Submissions of reviews and perspectives covering topics of current interest are welcome and encouraged. Reviews should be concise and no longer than 4-6 printed pages (about 12 to 18 manuscript pages). Reviews are also peer-reviewed.

Review Process
All manuscripts are reviewed by an editor and members of the Editorial Board or qualified outside reviewers. Authors cannot nominate reviewers. Only reviewers randomly selected from our database with specialization in the subject area will be contacted to evaluate the manuscripts. The process will be blind review.

Decisions will be made as rapidly as possible, and the journal strives to return reviewers’ comments to authors as fast as possible. The editorial board will re-review manuscripts that are accepted pending revision. It is the goal of the AJFS to publish manuscripts within weeks after submission.

Regular articles
All portions of the manuscript must be typed double-spaced and all pages numbered starting from the title page.

The Title should be a brief phrase describing the contents of the paper. The Title Page should include the authors' full names and affiliations, the name of the corresponding author along with phone, fax and E-mail information. Present addresses of authors should appear as a footnote.

The Abstract should be informative and completely self-explanatory, briefly present the topic, state the scope of the experiments, indicate significant data, and point out major findings and conclusions. The Abstract should be 100 to 200 words in length. Complete sentences, active verbs, and the third person should be used, and the abstract should be written in the past tense. Standard nomenclature should be used and abbreviations should be avoided. No literature should be cited. Following the abstract, about 3 to 10 key words that will provide indexing references should be listed.

A list of non-standard Abbreviations should be added. In general, non-standard abbreviations should be used only when the full term is very long and used often. Each abbreviation should be spelled out and introduced in parentheses the first time it is used in the text. Only recommended SI units should be used. Authors should use the solidus presentation (mg/ml). Standard abbreviations (such as ATP and DNA) need not be defined.

The Introduction should provide a clear statement of the problem, the relevant literature on the subject, and the proposed approach or solution. It should be understandable to colleagues from a broad range of scientific disciplines.

Materials and methods should be complete enough to allow experiments to be reproduced. However, only truly new procedures should be described in detail; previously published procedures should be cited, and important modifications of published procedures should be mentioned briefly. Capitalize trade names and include the manufacturer's name and address. Subheadings should be used. Methods in general use need not be described in detail.
Results should be presented with clarity and precision. The results should be written in the past tense when describing findings in the authors’ experiments. Previously published findings should be written in the present tense. Results should be explained, but largely without referring to the literature. Discussion, speculation and detailed interpretation of data should not be included in the Results but should be put into the Discussion section.

The Discussion should interpret the findings in view of the results obtained in this and in past studies on this topic. State the conclusions in a few sentences at the end of the paper. The Results and Discussion sections can include subheadings, and when appropriate, both sections can be combined.

The Acknowledgments of people, grants, funds, etc should be brief.

Tables should be kept to a minimum and be designed to be as simple as possible. Tables are to be typed double-spaced throughout, including headings and footnotes. Each table should be on a separate page, numbered consecutively in Arabic numerals and supplied with a heading and a legend. Tables should be self-explanatory without reference to the text. The details of the methods used in the experiments should preferably be described in the legend instead of in the text. The same data should not be presented in both table and graph form or repeated in the text.

Figure legends should be typed in numerical order on a separate sheet. Graphics should be prepared using applications capable of generating high resolution GIF, TIFF, JPEG or Powerpoint before pasting in the Microsoft Word manuscript file. Tables should be prepared in Microsoft Word. Use Arabic numerals to designate figures and upper case letters for their parts (Figure 1). Begin each legend with a title and include sufficient description so that the figure is understandable without reading the text of the manuscript. Information given in legends should not be repeated in the text.

References: In the text, a reference identified by means of an author’s name should be followed by the date of the reference in parentheses. When there are more than two authors, only the first author’s name should be mentioned, followed by ‘et al’. In the event that an author cited has had two or more works published during the same year, the reference, both in the text and in the reference list, should be identified by a lower case letter like ‘a’ and ‘b’ after the date to distinguish the works.

Examples:

Abayomi (2000), Agindotan et al. (2003), (Kelebeni, 1983), (Usman and Smith, 1992), (Chege, 1998; 1987a,b; Tijani, 1993,1995), (Kumasi et al., 2001)

References should be listed at the end of the paper in alphabetical order. Articles in preparation or articles submitted for publication, unpublished observations, personal communications, etc. should not be included in the reference list but should only be mentioned in the article text (e.g., A. Kingori, University of Nairobi, Kenya, personal communication). Journal names are abbreviated according to Chemical Abstracts. Authors are fully responsible for the accuracy of the references.

Examples:

Short Communications

Short Communications are limited to a maximum of two figures and one table. They should present a complete study that is more limited in scope than is found in full-length papers. The items of manuscript preparation listed above apply to Short Communications with the following differences: (1) Abstracts are limited to 100 words; (2) instead of a separate Materials and Methods section, experimental procedures may be incorporated into Figure Legends and Table footnotes; (3) Results and Discussion should be combined into a single section.

Proofs and Reprints: Electronic proofs will be sent (e-mail attachment) to the corresponding author as a PDF file. Page proofs are considered to be the final version of the manuscript. With the exception of typographical or minor clerical errors, no changes will be made in the manuscript at the proof stage.
**Fees and Charges**: Authors are required to pay a $650 handling fee. Publication of an article in the Journal of Microbiology and Antimicrobials is not contingent upon the author's ability to pay the charges. Neither is acceptance to pay the handling fee a guarantee that the paper will be accepted for publication. Authors may still request (in advance) that the editorial office waive some of the handling fee under special circumstances.

**Copyright**: © 2015, Academic Journals. All rights Reserved. In accessing this journal, you agree that you will access the contents for your own personal use but not for any commercial use. Any use and or copies of this Journal in whole or in part must include the customary bibliographic citation, including author attribution, date and article title.

Submission of a manuscript implies: that the work described has not been published before (except in the form of an abstract or as part of a published lecture, or thesis) that it is not under consideration for publication elsewhere; that if and when the manuscript is accepted for publication, the authors agree to automatic transfer of the copyright to the publisher.

**Disclaimer of Warranties**

In no event shall Academic Journals be liable for any special, incidental, indirect, or consequential damages of any kind arising out of or in connection with the use of the articles or other material derived from the JMA, whether or not advised of the possibility of damage, and on any theory of liability. This publication is provided "as is" without warranty of any kind, either expressed or implied, including, but not limited to, the implied warranties of merchantability, fitness for a particular purpose, or non-infringement. Descriptions of, or references to, products or publications does not imply endorsement of that product or publication. While every effort is made by Academic Journals to see that no inaccurate or misleading data, opinion or statements appear in this publication, they wish to make it clear that the data and opinions appearing in the articles and advertisements herein are the responsibility of the contributor or advertiser concerned. Academic Journals makes no warranty of any kind, either express or implied, regarding the quality, accuracy, availability, or validity of the data or information in this publication or of any other publication to which it may be linked.

Identification and genotypic analysis of *Streptococcus pyogenes* isolated from pharyngitis and tonsillitis infected children in IBB city in Yemen

Gamal A. AL-Ameri¹* and Abdu M. AL-Kolaibe²

¹Department of Medical Microbiology, College of Medicine, Taiz University, Yemen. ²Department of Microbiology, College of Science, Taiz University, Yemen.

Received 22 July, 2013; Accepted 24 February, 2015

*Streptococcus pyogenes* is beta-hemolytic bacterium that belongs to Lancefield serogroup A, also known as group A streptococci (GAS). GAS causes a wide variety of life threatening diseases including pharyngitis and tonsillitis disease. A total of 93 throat swab and 93 blood specimens were collected from pharyngitis and tonsillitis infected children in different schools in Almashana, IBB city in Yemen. All isolates were diagnosis by using two methods: throat swab culture and serological test (ASO test). The result shows difference between throat swab culture method and blood specimens serology method (ASO). 38 isolates (40.8%) for throat swab culture and 60 isolates (64.5%) for blood specimens serology method (ASO) were positive in 93 total isolates. All isolates were characterized by their antimicrobial susceptibility test to different antibiotics including penicillin G, chloramphenicol, erythromycin, clindamycin and streptomycin. All isolates were sensitive to penicillin G and chloramphenicol. Most isolates (61.3%) showed a high degree of resistance to erythromycin. Resistance to clindamycin and streptomycin were observed in 34.4 and 46.2% of isolates, respectively. The 93 isolates were subjected to fingerprinting by random amplified polymorphic DNA (RAPD) analysis. Amplification of genomic DNA of GAS was performed with three primers. The results reveal that approximately 36 different amplified DNA fragments (rapdemes) were observed in all, of which 21 (58.3%) were shared and 15 (41.7%) unshared or unique rapdemes. RAPD analysis provides a practical alternative for genomic typing of GAS. It can be recommended for the typing of GAS, especially if used in parallel with serotyping.

**Key words:** Group A streptococci (GAS), IBB city, antistreptolysin-O (ASO) test, pharyngitis, random amplified polymorphic DNA (RAPD).

INTRODUCTION

The Gram positive bacterium *Streptococcus pyogenes* has the ability to cause disease, both relatively mild local diseases as well as life-threatening invasive or systemic disease. *S. pyogenes* is beta-hemolytic bacterium that...
belongs to Lancefield serogroup A, also known as group A streptococci. They are classified based on their hemolytic capacity (α-, β-, γ-hemolysis) and the antigenicity of a carbohydrate occurring in their cell walls (Lancefield antigen) (Murray et al., 2002).

Group A streptococcus (GAS) elaborate several extracellular products include Streptolysin O (SLO) which derives its name from its oxygen lability. It is a member of a family of highly conserved pore-forming cytolytins. In addition to its effect on erythrocytes, it is toxic to a variety of cells and cell fractions, including PML, platelets, tissue-culture cells, lysosomes (Madden et al., 2001). The antistreptolysin-O (ASO) test is used to determine recent streptococcal infection and post streptococcal complications including rheumatic fever and glomerulonephritis. The presence and level of ASO antibodies in human serum directly reflects the extent and degree of infection. Elevated levels of ASO may also be present in other conditions including scarlet fever, acute rheumatoid arthritis, tonsillitis and various other streptococcal infections as well as in health carriers (Johnson et al., 1996).

S. pyogenes is the cause of many human diseases, ranging from mild superficial skin infections to life-threatening systemic diseases. Pharyngitis is the most common clinical manifestation of S. pyogenes infection.

The diagnosis of GAS is necessary to demonstrate evidence of recent infection. This can be established in one of the three ways: (a) positive throat culture, (b) positive group A streptococcal antigen test from throat swab, or (c) elevated or rising serum antistreptococcal antibody titer. The antistreptolysin-O (ASO) titer is a commonly used streptococcal antibody test in establishing the diagnosis of these bacteria (Kaplan et al., 1992; Seppala et al., 1994).

Therefore, a number of genotyping techniques like ribotyping (Shundi et al., 2000), pulse field gel electrophoresis (Gonzalez–Rey et al., 2003), random amplified polymorphic DNA (RAPD) analysis (Gonzalez–Rey et al., 2003; Fica et al., 2003) are being applied worldwide for typing of GAS isolates. RAPD typing was found to be a simple, rapid, effective method for the epidemiological investigation of any outbreak for the study of S. pyogenes infections (Cleary et al., 1988).

The present work aimed to: 1) Determine the prevalence of Streptococcus group (A) among pharyngitis and tonsillitis infected children in different schools in Almashana region in IBB city in Yemen by using two methods; throat swab culture and serological test (ASO test); 2) Determine the susceptibility of all bacteria isolates to various antibiotics; 3) Fingerprint the genetic variation among all bacteria isolates by using the RAPD.

MATERIALS AND METHODS

Bacterial isolates
A total of 93 throat swab and blood specimens were collected from same children patients (aged 6 to 15 years) from Almashana in IBB city during April 2012 to December 2012 (during the winter). The isolates were identified as S. pyogenes by colony morphology, β-haemolysis on sheep blood agar, and Lancefield grouping by using a commercially available agglutination technique (Seroiden Strepto kit) and bacitracin disc test (0.04 U, Taxo A, BBL Microbiology system) (Bisno, 1996; Gerber, 1984).

Antimicrobial susceptibility testing
Antibiotic susceptibility testing was performed by Kirby-Bauer disk diffusion according to the guidelines recommended by the CLSI (1990); the examined antibiotic disks contained penicillin, chloramphenicol, erythromycin, clindamycin and streptomycin (HiMedia) (Snow et al., 2001).

Molecular fingerprinting for the S. pyogenes 93 bacterial isolates
Genomic DNA was extracted from overnight cultures using the Wizard Genomic DNA Purification kit (Promega) according to the manufacturer’s instructions. Random amplified polymorphic DNA was performed on all the isolates using three random primers in three separate RAPD-PCR tests in an effort to type S. pyogenes isolates: Primers EZ (5'-GCATCACAGACCTGGATTTG CCCT3'), OPA14 (5'-GACCGCTTGT-3') and OPA13 (5'-CAGCACCAC-3') [Operon Technologies, Inc., Atlanta, USA] (Martin and Single, 1993; Micheli et al., 1993). RAPD-PCR was carried out in a 25 μl reaction mixture containing 2.5 μl 10x buffer, 0.2 mM dNTPs, 0.5-1 μl (100 pmol) primer, 2 U Taq DNA polymerase, 3.0 mM MgCl2, 50 ng DNA template and nuclease-free water. Amplification conditions consisted of denaturation at 95°C for 5 min and 40 cycles of denaturation at 95°C for 1 min, annealing at 43°C for 1 min and extension at 72°C for 1 min with a final extension at 72°C for 10 min. PCR products were detected in 2% agarose gel. A 100-bp ladder was used in each gel as a DNA fragment size marker. After staining with ethidium bromide, PCR products were photographed with UV light. The arbitrarily primed PCR patterns were examined by direct visual comparison of the patterns and the 100-bp ladder. In repeated analyses of selected GAS isolates, the results obtained with RAPD analysis were found to be reproducible (Martin and Single, 1993; Micheli et al., 1993; Penner et al., 1993).

RESULTS

Identification of throat swab by culture
In this study, 93 throat swab were collected from children to investigation the GAS from different school of Al-Mashana district in IBB city (Table 1). These specimens were collected according to the recommendation of the public health official in IBB Province. Table 1 shows the distribution of GAS at Almashana district. These specimens were collected in six schools of Almashana district as follows: 1) AL-thawr, 2) AL-shaab, 3) Khaled ben alwaleed, 4) Labusa society, 5) AL-kimma and 6) KL-manahel.

The result of throat swab culture was reported from a total of 93 specimens, 38 (40.8%) only represent S. pyogenes. This result is based on β-haemolytic and bacitracin disc sensitivity. Whereas 55 (59.2) was
Table 1. Disc sensitivity test against the isolated specimens. The results of throat specimens are shown for culture in blood agar.

*P, penicillin; C, chloramphenicol; E, erythromycin; Cl, clindamycin; S, streptomycin.

Negative as show in Table 3. The result reports high prevalence of GAS in Khaled ben Alwaleed, fourteen specimens out of the 20 specimens (70%), then AL-thawrh and Al-Shab schools with 16 specimens out of twenty four specimens (66.6%), followed by Labusa society with 11 out of 17 specimens (64.7%) and Al-kimma with two out of five specimens (40%); finally, Al-manahel with one out of three specimens (33.3%) as show in Table 4.

Relationship between throat swab culture and serology diagnostic test

The result shows difference between the diagnosis by throat swab culture method and blood specimens serology method. ASO positivity ratios are very high. Thirty eight (38) specimens were positive from 93 total specimens (40.8%) for culture method and 60 specimens were positive from 93 total specimens (64.5%) for serology method (ASO) as show in Table 5.

Susceptibility of *S. pyogenes* to antibiotics

The susceptibility of the all bacteria isolates (93) to antibiotics were tested by disk diffusion methods (Table 6). All clinical *S. pyogenes* were sensitive to penicillin G and chloramphenicol, 61.3% (57) were resistant to erythromycin.

Resistance to clindamycin and streptomycin were
observed in 34.4 and 46.2% of isolates, respectively.

**RAPD analysis**

RAPD analysis of 93 isolates was carried out using 3 different primers. RAPD fingerprinting showed highly polymorphic nature of the isolates. The results revealed that approximately 36 different amplified DNA fragments (rapdemes) were observed in all, of which 21 (58.3%) were shared and 15 (41.7%) unshared or unique rapdemes representing a 41.7% overall genetic heterogeneity among the isolates. The primer OPA14 and OPA13 revealed more discrimination as compared to EZ primer. As shown in Figure 2a-c, OPA14 and OPA13 resulted in 12 to 13 patterns, and EZ9 patterns. Hence, the primer OPA14 and OPA13 provided the higher level of discrimination.

**DISCUSSION**

GAS has continued to be a major health problem in developing and industrialized countries, especially since the outbreaks that emphasized the need for practitioners to remain vigilant and to maintain prevention efforts (David, 1998). In contrast to the developed countries, this disease has remained a significant problem for years in developing countries (Zangwill et al., 1991); furthermore, the overall quality of epidemiological data from developing countries is poor, particularly with respect to research documenting the incidence of GAS (Carapetis, 2004; Cunningham, 2000).

Diagnosis of GAS based on anti-streptolysin O alone is not reasonable unless throat culture is not performed because ASO test represent the former GAS infections, not acute infections and cross infection for ASO (IgG antibody) (Atatoa-Carr et al., 2008; Gerber, 1989).

Serological diagnosis of group A streptococcal infection is based on immune responses against the extracellular products streptolysin O which induce strong immune responses in the infected host. Anti-streptolysin O is the antibody response most often examined in serological tests to confirm antecedent streptococcal infection (Gerber, 1989; Gerber and Shulman, 2004). Numerous studies have demonstrated that the currently available rapid streptococcal tests have a sensitivity of 70-90% when compared with standard throat cultures. In contrast to their relatively low sensitivity, the specificity of these rapid tests has consistently been 90-100%. Therefore, if a rapid streptococcal test result is positive, a culture is not necessary, and appropriate antibiotic therapy is immediately initiated. However, when a negative result is encountered, a standard throat culture should always be obtained.

In this study, two methods were used to diagnose S. pyogenes: ASO test and throat swab culture. We found the ASO positivity ratios are very high but throat swab culture was more accurate than ASO test because the ASO test represent chronic infections or carrier of S. pyogenes, also due to the cross infection for ASO (IgG antibody). Thirty-eight (38) specimens were positive from 93 total specimens (40.8%) for culture method and 60 specimens were positive from 93 total specimens (64.5%) for serology method (ASO).

ASO test currently available were used when compared with blood agar plate cultures (Tanz et al., 2009; Johnson and Kaplan, 2001). False-positive test results are highly unusual, and therefore therapeutic decisions can be made with confidence based on a positive test result (Gerber and Shulman, 2004; Tanz et al., 2009; Johnson and Kaplan, 2001). Unfortunately, the sensitivity of most of these tests is 70-90%, when compared with blood agar plate culture (Gerber and Shulman, 2004; Tanz et al., 2009).

The culture result reported high prevalence of GAS in
AL-thawr, 12 cases from 24 specimens (50%), then AL-Shab with ten cases out of 24 specimens (41.6%), followed by Khaled ben Alwaleed with eight out of twenty specimens (40%) and Labusa society with five out of seventeen specimens (29%). Whereas, ASO test result reported high prevalence of GAS in Khaled ben Alwaleed school with fourteen out of twenty specimens (70%), then AL-thawr and AL-Shab schools with sixteen out of twenty four specimens (66.6%), followed by Labusa society with eleven out of seventeen specimens (64.7%) and Al-kimma with two out of five specimens (40%); finally, Al-manahel with one out of three specimens (33.3%) as show in Table 4 and Figure 3. The highest percentage of S. pyogenes infection in Althawra and Khaled ben Alwaleed school may be due to crowding of students in these schools. A number of antibiotics showed to be effective in treating GAS pharyngitis (Table 6). These include penicillin G and chloramphenicol. All isolates were sensitive to penicillin G and chloramphenicol, similar result was reported in USA and other countries (Shulman et al., 2012). Most of the isolates (68.8%) showed a high degree of resistance to tetracycline followed by 61.3% resistant to erythromycin. Resistance to clindamycin and streptomycin were observed in 34.4 and 46.2% of isolates, respectively; a similar study was reported in Korea (Sook et al., 2007). Clindamycin resistance among GAS isolates in the United States is approximately 1%, and this is a reasonable agent for treating penicillin-allergic patients (Tanz et al., 2004). RAPD method, based in PCR, was used for typing of GAS and it was found to be highly discriminatory. As reported earlier, selection of primers, optimization of PCR condition and combination of different primers play an important role in discriminating the isolates by RAPD (Micheli et al., 1993; Penner et al., 1993; Matthews, 1993). Hence, three arbitrarily selected primers (OPA14, OPA13 and EZ) were tested. The majority of arbitrary primers used, produced distinctly reproducible patterns in all the isolates studied. The results revealed that approximately 36 different amplified DNA fragments (haplotypes) were observed in all, of which 21 (58.3%) were shared and 15 (41.7%) unshared or unique patterns. According to these results, we have found the relationship between genetic diversity and antibiotic susceptibility of S. pyogenes isolates.

In conclusion, under carefully controlled spreading of the S. pyogenes infection, the results indicate the high prevalence of resistant S. pyogenes in patients for tetracycline and erythromycin 68.8 and 61.3% isolates, respectively. Therefore, the choice of the suitable antibiotic for the treatment of S. pyogenes infections should be made carefully to avoid the emergence of resistance isolates. The findings of this study demonstrated the benefit of RAPD fingerprinting (genotype) in comparison with phenotype methods in identifying and characterizing GAS isolates obtained from pharyngitis cases.

The yeast Candida is a normal flora of the skin and the mucous membrane and it then becomes pathogen in immunocompromised people. Various virulence factors are contributing to establishment of the infection in the host. Adherence of the pathogen to host tissues, yeast-hyphal transition and extracellular hydrolytic enzymes secretion are important virulence factors of Candida species. These hydrolytic enzymes play important roles in pathogenicity of Candida infection. The present study was conducted with an aim to determine in vitro phospholipase, proteinase, haemolysin, esterase activities and biofilm formation in oral Candida isolates. A total of 38 Candida species were isolated from oral cavity of patients with symptoms of oral candidiasis. The specimens were identified by standard mycological techniques up to species level and were investigated for production of hydrolytic enzymes and biofilm formation. Phospholipase activity was in 52.6% of isolates, 86.8% produced proteinase and haemolysin activity was seen in 63.1%, esterase activity was demonstrated in 50% of isolates, 78.9% of Candida isolates showed biofilm formation. Candida albicans showed more extracellular hydrolytic enzyme activity, whereas, Candida tropicalis showed more biofilm formation. Both the C. albicans and Non-albicans Candida (NAC) species are capable of producing extracellular hydrolytic enzymes and biofilm formation.

Key words: Candida species, virulence factors, extracellular hydrolytic enzymes, biofilm formation.

INTRODUCTION

The dimorphic fungus Candida sp. can respond rapidly to environmental changes, and this flexibility could allow this organism to take advantage of impaired immunity and facilitate establishment of disease. Although Candida is normal flora of skin and mucous membranes of healthy people, they cause infections that range from superficial infections to life-threatening systemic infections in immunocompromised and immunosuppressed people. Various virulence factors are contributing to the colonization and pathogenicity of Candida infection, including the expression of adhesins and invasins on the cell surface, yeast-hyphal morphogenetic transformation, the formation of biofilms, phenotypic switching and the secretion of hydrolytic enzymes (Francois et al., 2013).

Among the various factors, extracellular hydrolytic enzymes of which SAPs (secreted aspartyl proteinases) are considered to be one of the major virulence factors play a major role in overgrowth of the *Candida*, since these enzymes pave way to adhere, penetrate and for tissue invasion (Schaller et al., 2005).

Aspartyl proteinases are secreted by pathogenic species of *Candida in vivo* during infection. The enzymes are secreted *in vitro* when the organism is cultured in the presence of exogenous protein (usually bovine serum albumin) as the nitrogen source. Phospholipase enzymes, another important virulence factor, are associated with the function related to host cell damage, adherence and penetration (Kabir et al., 2012). They destroy phospholipids in the host cell, hence results in the damage to the cell membrane, cell lysis and facilitating tissue invasion (Bhat et al., 2011). There are four secreted phospholipase, A to D (PLA, PLB, PLC and PLD). Their activity is very high during tissue damage because these enzymes carry out hydrolysis of one or more ester linkages of glycerophospholipids on the host cell membrane. Furthermore, *Candida albicans* is able to acquire elemental iron from host tissues through haemolysin production, iron chelators (siderophores) and iron-transport proteins, which then is used by the fungus for metabolism, growth and establishment of infection in humans (Weinberg, 1978; Almeida et al., 2009). The ability of *C. albicans* to utilize hemoglobin as an iron source was first described by Moors et al. (1992). In humans, iron is found in some proteins, including hemoglobin (a component of erythrocytes). The first step of *C. albicans* infection *in vivo* involves binding to erythrocytes through receptors of the complement system. Next, *C. albicans* produces a hemolysis factor that induces lysis of the erythrocyte. This factor most likely corresponds to a mannoprotein bound to the cell surface of the fungus (Almeida et al., 2009; Watanabe et al., 1999). Almeida et al. (2008) observed that *C. albicans* caused greater damage to oral epithelial cells containing elevated concentrations of ferritin as compared to cells with lower iron levels.

Traditionally, antifungal drugs were developed either to inhibit or to kill the pathogenic organism. Because of the development of anti fungal resistance to various anti fungal drugs by the pathogen, there is a need to develop new antifungal strategy which specifically targets the virulence factors. The study of virulence factors provides a way to specifically target virulence of *Candida* sp. Therefore, the present study was conducted with an aim to determine *in vitro* phospholipase, proteinase, haemolysin, esterase activities and biofilm formation in oral *Candida* isolates.

**MATERIALS AND METHODS**

**Collection of samples**

A total of 38 clinical samples were obtained from patients attending Tertiary Care Hospitals, Coimbatore, TamilNadu, India, with symptoms of oral candidiasis. Oral swabs were collected with all aseptic precautions using sterile swabs from tongue and buccal mucosa by gently rubbing over the lesional tissue. The swabs were then dispersed in a test tube containing sterile SDA broth. Then, they were identified by Gram staining, lactophenol cotton blue test, germ tube test, carbohydrate fermentation test; urease test, morphology on HiCHROM agar and corn-meal agar with Tween-80. Culture on *Candida* HiCHROM agar was for the species identification whereas corn-meal agar was for demonstration of chlamydospores.

**Preparation of the yeast suspension**

Yeast suspension was prepared from the isolates. A small amount of stock culture was inoculated on Sabouraud dextrose agar (SDA) containing chloramphenicol by using a sterile loop and incubated at 37°C for 24-48 h. Then, the yeasts were harvested and suspended in sterile phosphate buffered solution (PBS) at turbidity equal to optical density (OD) of 0.5 McFarland. The final suspension was adjusted to contain 1 x 10^7 yeast cells/ml.

**Determination of phospholipase activity**

The extracellular phospholipase activity of *Candida* sp. was determined by growing them on egg yolk agar and measuring the size of zone of precipitation by the method prescribed by Samaranayake et al. (1984). The egg yolk medium was prepared according to Tsang et al. (2007) and Mohandas (2011). A 10 ml suspension of yeast cells per ml saline was placed on the egg yolk medium and left to dry at room temperature. The culture was then incubated at 37°C for 48 h, after which the diameter of the precipitation zone around the colony was determined. Phospholipase activity was measured by dividing colony diameter by the diameter of the precipitation zone (pz) around the colony formed on the plate. The pz was scored as follows: pz = 1, negative phospholipase activity; pz = 0.64-0.99, positive phospholipase activity; and pz ≤ 0.63, very strong phospholipase activity (Price et al., 1982). The lower the pz value, the higher the enzymatic activity.

**Determination of protease activity**

Extracellular protease activity of *Candida* sp. was analyzed in terms of bovine serum albumin (BSA) degradation by the technique described by Staib et al. (1965). To determine proteinase activity, bovine-serum albumin agar (0.1% KH_2PO_4, 0.05% MgSO_4, 4% agar and 1% bovine serum albumin) was employed (Tsang et al., 2007). The final pH was adjusted to 4.5. Ten microliters of previously prepared yeast suspension was inoculated into the wells punched onto the surface of the medium onto the plates; these were then incubated at 37°C for 10 days in both aerobic and anaerobic conditions. After incubation, the plates were fixed with 20% trichloracetic acid and stained with 1.25% amidoblack. Decolourization was performed with 15% acetic acid. Opaque zones of the agar, corresponding to a zone of proteolysis around the wells that could not be stained with amido black, indicated degradation of the protein. The presence of proteinase activity was determined by the formation of a transparent halo around the yeast colonies. The diameter of unstained zones around the well was considered as a measure of protease production. The proteinase activity (Prz) was determined in terms of the ratio of the diameter of the well to the diameter of the proteolytic unstained zone. Proteinase activity (Prz) was determined by the method described by Price et al. (1982). Prz was scored as follows: Prz = 1, negative proteinase activity, Prz =...

0.64-0.99, positive proteinase activity; and Pr$_2$ ≤ 0.63, very strong proteinase activity. Thus, a low Pr$_2$ indicated high production of the enzyme.

**RESULTS AND DISCUSSION**

Of the 38 isolates, 22 isolates (58%) were identified as C. albicans, while 9 (24%) were identified as Candida tropicalis, 6 (16%) as Candida krusei, 1 (2%) as Candida glabrata (Table 1). These isolates were studied for the production of hydrolytic enzymes such as phospholipase, proteinase, esterase, haemolytic activity and for the biofilm formation (Figure 1).

Phospholipase activity was found in 20 (52.6%) isolates and positivity for proteinase activity was found in 33 (86.8%) Candida isolates. Hemolysin activity was seen in 24 (63.1%) isolates and esterase activity was found in 19 (50%). About 30 (78.9%) isolates gave positive result for biofilm formation. Maximum phospholipase (100%) activity and esterase activity (59%) was seen in C. albicans whereas maximum proteinase (100%) activity, haemolysin (77.7%) production and biofilm formation (88.8%) was seen in C. tropicalis. C. krusei and C. glabrata also showed positive results for all the activities (Table 1).

C. albicans is an opportunistic pathogenic microorganism that has developed several virulence factors facilitating the invasion of host tissues (Schaller et al., 2005). The ability of Candida species to persist on mucosal surfaces of healthy individuals is an important factor contributing to its virulence. This is particularly important in the oral cavity, where the organism has to resist the mechanical washing action of a relatively constant flow of saliva toward the esophagus (Sithuee and Samaranayake, 2003). Various virulence factors contribute to the colonization and pathogenicity of C. albicans infection, including the expression of adhesins and invasins on the cell surface (Cannon and Chaffin, 1999), yeast-hyphal morphogenetic transformation, phenotypic switching (Francois et al., 2013), the secretion of hydrolytic enzymes (Schaller et al., 2005), iron acquisition from the environment (Manns et al., 1994), the ability to form biofilm on various surfaces (Williams and Lewis, 2011).

Many different hydrolytic enzymes are identified in...
Candida sp. including secreted aspartyl proteinase, phospholipase, lipase and esterase. The production of hydrolytic enzymes helps in colonization of host surfaces, increase adhesion by degrading host surface molecules, allow penetration into host tissues by digesting host cell membranes or evasion of host defense mechanism by digesting cells and molecules of the host immune system hence modulate host immune responses (Calderone et al., 2002).

It has been reported that the enzymatic activity of Candida sp. may vary depending on the species and source of isolates (Mohandas and Ballal, 2002). In this study, out of 38 isolates, phospholipase activity was detected in 100% of the C. albicans. Tsang et al. (2007) also reported the same positivity rate of phospholipase activity, in samples from patients with oral Candida infection. Previous studies have reported phospholipase activity in 30 to 100% of Candidal isolates from various groups of patients and from various sites (Price et al., 1982; Wu et al., 1996). As shown in Table 1, 100% of C. albicans produced phospholipase, among the NAC species, C. tropicalis followed by C. krusei showed maximum phospholipase production. Phospholipase enzyme digests the host cell membrane phospholipid causing cell lysis and changes in the surface features that enhance adherence and consequent infection and hence phospholipase production may be used as one of the parameters to distinguish virulent invasive strains from non-invasive colonisers. About 90.9% of C. albicans showed proteolytic activity in the present study. C. tropicalis showed 100% proteolytic activity followed by C. krusei. This observation was similar to the reports given by previous workers (Marcos-arias et al., 2011).

It was noted that haemolysin activity was higher in C. tropicalis (77.7%) followed by C. albicans (63.63%). Manns et al. (1994) defined the condition under which C. albicans can display haemolytic activity and found that haemolysis is non-existent when no glucose is available in the culture medium. Rossoni et al. (2013) found that non-Candida species also produced same haemolytic activity as C. albicans. C. albicans secretes a haemolytic factor that causes the release of haemoglobin, which is then used as an iron source by the organisms. Watanabe et al. (1999) demonstrated that mannoprotein released from C. albicans bound to the band 3 protein on RBCs, thereby promoting their disruption. They detected the haemolytic activity in the culture supernatant of C. albicans in vitro. In the oral cavity, extracellular iron is bound mainly to lactoferrin, a protein present in saliva, while intracellular iron is stored as ferritin. Although, this element is bound to proteins and/or is present in the cytoplasm of cells, oral infections with C. albicans are frequent, suggesting that this yeast is able to take up different forms of iron from the oral cavity (Almeida et al., 2008).

About 59% of C. albicans expressed esterase activity (Pakshir et al., 2013; Aktas et al., 2002). It has been reported that both C. albicans and non-albicans Candida sp. express esterase activity. Rudek et al. (1978) demonstrated that esterase activity would appear to be a common feature of Candida species that are frequently isolated from clinical specimens. Kumar et al. (2006) reported that Tween 80 opacity test cannot be used as the sole phenotypic trait in the differentiation of C. albicans and C. dubliicantis though it appears to be simple, economical and easy method to perform for use in small clinical laboratories. Melak et al. (2012) detected that C. albicans showed esterase activity in aerobic conditions but not in anaerobic conditions.

Biofilm formation is one of the most important virulence factors of Candida sp. (Figure 1). Candida biofilms occur on tissue surfaces as well as the biomaterials of medical devices. As reported by Gultekin et al. (2011), no biofilm formation was detected in any C. albicans strains by
microplate method, while it was found in 50% of non-
albicans Candida sp. Demirbilek et al. (2007) also
detected that the biofilm formation rate was higher in non-
albicans Candida sp. than in C. albicans strains by the
microplate method. In our study, the biofilm formation
rates were found to be higher in C. tropicalis (88.8%) than C. albicans (86.3%). According to the above
mentioned studies, the biofilm formation rate was higher
in non-albicans Candida species as compared to C. albicans isolates.

Conclusion
It is necessary to understand the pathogenicity
mechanisms of the Candida sp. for the development of new antifungal strategy. Developing antifungal therapies
against selective target virulence factor is very crucial
nowadays because of the multi-drug resistance
developed by Candida sp. Hence, our study on virulence
factors of Candida sp. pave way for the better understanding of the various virulence factors exhibited
by Candida sp.
