ABOUT AJPP

The African Journal of Pharmacy and Pharmacology (AJPP) is published weekly (one volume per year) by Academic Journals.

African Journal of Pharmacy and Pharmacology (AJPP) is an open access journal that provides rapid publication (weekly) of articles in all areas of Pharmaceutical Science such as Pharmaceutical Microbiology, Pharmaceutical Raw Material Science, Formulations, Molecular modeling, Health sector Reforms, Drug Delivery, Pharmacokinetics and Pharmacodynamics, Pharmacognosy, Social and Administrative Pharmacy, Pharmaceutics and Pharmaceutical Microbiology, Herbal Medicines research, Pharmaceutical Raw Materials development/utilization, Novel drug delivery systems, Polymer/Cosmetic Science, Food/Drug Interaction, Herbal drugs evaluation, Physical Pharmaceutics, Medication management, Cosmetic Science, pharmaceuticals, pharmacology, pharmaceutical research etc. The Journal welcomes the submission of manuscripts that meet the general criteria of significance and scientific excellence. Papers will be published shortly after acceptance. All articles published in AJPP are peer-reviewed.

Submission of Manuscript

Submit manuscripts as e-mail attachment to the Editorial Office at: ajpp@academicjournals.org. A manuscript number will be mailed to the corresponding author shortly after submission.

The African Journal of Pharmacy and Pharmacology will only accept manuscripts submitted as e-mail attachments.

Please read the Instructions for Authors before submitting your manuscript. The manuscript files should be given the last name of the first author.

Received 16 May, 2015; Accepted 5 June, 2015

The tannic acid is a polyphenol with several properties that give it different applications, including leather and pharmaceutical industry. It belongs to the group of water soluble metabolites, and has the ability to complex macromolecules and metal ions, which gives it antioxidant, antimicrobial and healing activity. Therefore, such properties can be used to develop technologies related to wound healing systems. This prospective study summarizes bibliographic information about the use of tannic acid in topical formulations for healing skin wounds. The data were collected through the search tool available in patent databases (INPI, USPTO, EPO, WIPO, DERWENT) and articles (Web of Science) about the application of tannic acid in skin wound healing system. In recent decades, there has been growth in number of searches for elucidation of antimicrobial and antioxidant activities of tannic acid, and its incorporation in biomaterials in the pharmaceutical field. The United States, Japan and China stood out in inventions and publishing articles. The Brazilian biodiversity is immense, although underexplored and poorly study about extraction and properties of tannins in topical formulations, which lacks encourages to research technologies for healing system more effective and cheap.

Key words: Tannic acid, cutaneous healing system, technological prospecting.

INTRODUCTION

Natural products are raw materials of great interest for different industrial sectors, due to the fact that it presents in its composition a variety of active ingredients. The tannins, for example, have applications in ecological agriculture, preparation of flocculants for water and effluent treatment, obtaining natural polymers, wine clarification, biomaterials, etc. In almost all botanical families there are species that contain tannins. When they occur in large quantities, the tannins are usually located in certain parts of the plant as the roots, bark, leaves, fruits, seeds and sap (Claus and Tyler, 1965). Tannins belong to a group of phenolic compounds from the secondary metabolism of plants. They have a high molecular weight (500 to 3000 Da) and contain phenolic hydroxyl groups in sufficient amounts to allow crosslinking to macromolecules (Min et al., 2003). They are classified into two groups: hydrolysable tannins and condensed tannins.

The tannic acid is water-soluble tannin, comprising a central glucose molecule attached with five chains formed...
by two esterified gallic acid molecules. In an acid medium, in mild alkaline conditions or under the action of enzymes (such as tannase), the tannic acid can undergo hydrolysis obtaining carbohydrates (glucose) and phenolic acids (gallic acid, especially) (Bruneton, 2001).

The tannic acid is considered a safe food additive (Akiyama et al., 2001). Moreover, the tannin has astringent and antibacterial properties, and it can be used as a medicament against diarrhea, hemostatic, anti-hemorrhoid formulations, in the treatment of skin ulcers, wounds and toothache (Aeleneti et al., 2009). However, this compound should not be used in large quantities because it inhibits the absorption of iron in the body (Chung et al., 1998).

In previous studies, the tannic acid showed antimicrobial activity against pathogens (Chung et al., 1998; Scalbert, 1991). Research with the seed extract of Vitis rotundifolia species showed that tannic acid was the main chemical constituent responsible for its antimicrobial properties (Kim et al., 2008). The pure tannic acid when subjected to heat treatment, its antimicrobial activity is significantly increased (Kim et al., 2010). Among the polyphenols, the tannic acid and quercetin were considered the constituents of higher antioxidant capacity (Pulido et al., 2000).

Plants rich in tannins are used in the traditional medicine as drugs for the treatment of various organic diseases, including the healing process of wounds, burns, and inflammation (Haslam, 1996). This is explained because of its property of complexing proteins at the injury site. The tannins form complex with macromolecules (proteins and/or polysaccharides) providing a protective layer on the epithelial tissues injured; the healing process of the wound occurs naturally just below this layer (Monteiro et al., 2005).

In Brazil, there is an increasing public spending on treatment of skin lesions, especially the wounds originating from chronic diseases such as Diabetes mellitus, considered difficult to heal. Investigations on the pharmacological and biological activities of tannins, more specifically the tannic acid, can contribute to the technological development of cheaper and effective curative systems for skin lesions. In this context, this study aimed to perform a technological prospecting on the incorporation of tannic acid in formulations for topical use in wound healing process.

**MATERIALS AND METHODS**

The prospecting was conducted based on the patent applications filed at the National Institute Database of Industrial Property (INPI), European Patent Office (EPO), United States Patent and Trademark Office (USPTO), World Intellectual Property Organization (WIPO) and Derwent Innovations Index. Also, the study investigated the publication of articles on the basis of the Web of Science. The key words used in the search are listed in Table 1. In this research, were considered valid documents that submitted key words in the "title" and/or "abstract". This prospective study was conducted in March, 2015 and included the years available at the databases until now. With regard to the articles, the discussion was based on the technological field, country, year of publication and the bibliographic review.

**RESULTS AND DISCUSSION**

**National institute of industrial property (INPI) database**

The patent search in the INPI using the term "tannic acid" resulted in 15,025 patents. In the analyze of the abstracts noted that the search results generated with patents that only included the word "acid", and that did not match the tannic acid. So the study chose to use only the term "tannic" to refine the search, culminating in 18 patents. The deposit period of these patents was between the years 1991 to 2014. Brazil and the United States were the countries with the highest depositors numbers with 7 and 5 patents, respectively. Countries like Japan, Italy, Mexico, Argentina and Belgium also had depositors patents in INPI.

The international patent classification (IPC) classifies the invention according to different technological fields to which the invention pertains. The A61K code had the highest number of patent applications (Figure 1). This IPC is related to the area of preparations for medical purposes, dental or hygienic purposes in Human Needs section. For example, the patent CI 0400241-5 (Marques, 2005) have A61K classification and describes a formulation for tattoo removal, stretch marks, scars, keloid, vitiligo, sunburn and any visible mark characterizing a skin lesion. It consists of tannic acid and water, may be present as liquid, creamy, paste or gel forms. When applied to the skin, this product causes local inflammation that causes pigments that migrate to form a scab that detached part of the dermis caring 50 to 100% of the tattoo pigment.

The PI 9811478-6 (Lener et al., 1998), invention, also A61K IPC, refers to the controlled or sustained release compositions of pharmaceutical agents that include one or more cellulose polymers (hydroxyethyl cellulose, hydroxypropyl cellulose or hydroxypropyl methylcellulose) or proteinaceous (gelatin or collagen), and tannic acid or other tannin. The agent's field of action is topical, local or systemic. The tannic acid when combined with these polymers can make it more resistant to proteolytic enzymes, and when applied to living tissue have astringent action, which is the therapeutic application base of tannins.

Falcon (1998), in his PI 9811875-7 invention, discloses a pharmaceutical composition based in tannic acid which can be used to treat any cancer condition. The formulation is composed of tannic acid, sorbitol, castor bean oil, potassium sorbate, methylparaben and propylparaben, and can be used in the form of tablets, capsules, solutions or suspensions. Degenerative diseases such as cancer, are associated with high intercellular concentrations of reactive oxygen species or

Figure 1. IPC by number of patents.

free radicals. It is then suggested that the tannic acid acts as a free radical scavenger, which intercepts the active oxygen to form stable free radicals. It has the ability of inhibiting lipid oxidation by removing free radicals (Sanchez-Moreno et al., 1999; Gülçin et al., 2010).

The A01N and A23L classifications have around 18 patent applications, which also comprise human needs. The A01N IPC comprises biocidal formulations as disinfectants, herbicides, pesticides, repellents, and plant growth regulators. The field of preparing, processing and storage of food and non-alcoholic beverages is represented by A23L IPC.

United States patent and trademark office (USPTO) database

On the databases of the USPTO were found 85 patent (Table 1) for the term "tannic acid". Among the countries of the depositors' origins, Canada stood out with 16 patents, followed by Gabon and Japan with 12 and 10 patents, respectively. The publication period included the years between 2001 to 2014 (Figure 2), in 2004 were 10 patents and in 2013, totaled 9 published patent applications. The patent application filed in 2015 included compositions to increase the selenium and lithium content in vegetables and processed products. The abstracts revealed that 62% of patents found were related to medical sciences or veterinary and hygiene.

The refined patent search using the terms "wound and healing" did not obtain any patent result that had tannic acid involved in the wound healing process. Although the two terms have not appeared in the title or abstract, some patents made use of tannic acid with dermatological purposes. Murard (2006), proposed a pharmaceutical composition for cleaning the skin to facilitate the prevention, treatment, and management of skin diseases, such as seborrheic dermatitis, psoriasis, folliculitis, rosacea, perioral dermatitis, acne and other inflammatory skin conditions, including a sufficient amount of a hydroxy acid or tannic acid, or a pharmaceutically acceptable salt thereof. Mitts et al. (2014), have formulated compositions containing polyphenol of ellagic acid and/or tannic acid for skin protection against degradation of elastic fibers by skin enzymes that act to promote total deposition of elastic fibers in skin cells. Hamtini (2004), developed a
rash treatment product consisting of salicylic acid, boric acid, tannic acid, zinc oxide, calamine and lanolin, castor oil or cod liver oil. In this case, the exposed tissue proteins precipitate and form a antiseptic protective layer promoting the tissue regeneration.

The only patent found with a combination of tannic acid and carboxymethylcellulose terms, discoursed about an invention for the treatment of soil (Ballard, 2007). The use of organic acids have great interference in sorption/desorption processes of cations and anions, in the microbial activity, and in the metabolic disposition of carbonaceous substrate with a direct effect on soil fertility.

World intellectual property organization (WIPO) database

In the WIPO database, 1074 patents were found with the use of the "tannic acid" term in the title and/or abstract. China is the country with the largest number of applications filed (287), followed by Japan (214) and United States (205) (Figure 3). The inventions stood out in the category of human needs with the A61K, A61P and A23L IPC (Figure 4). As mentioned before, the rating A61K covers the sub-area of medical science or dental and hygiene; A61P is the sub-area of specific therapeutic activity of chemical compounds or medicinal preparations, and A23L refers to processes, treating and storage of food products and non-alcoholic beverages. The publication period was between the years 1990 to 2014. The largest number of patent applications occurred in the years 2014 and 2008 with 68 cases, followed by 2000, 2007 and 2009 with 67, 58 and 54 patents, in that order. It was observed in the last two decades an increasing in research that explore the physical, chemical, biological and pharmacological properties of tannic acid. Its application versatility can be attributed to three general characteristics of tannins: complexation with metal ions, oxidant activity and scavenging of free radicals, and the ability to form complexes with macromolecules (Bruneton, 2001). The search resulted in 3 patents with combination of the words "tannic acid and wound" in which contemplated formulations for: wound healing in horses, second degree burns and hemorrhoids treatment. Using the term "healing", 5 patents were obtained as a result of the search. The inventions have applications in wound healing in the form of ointment, chewing gum (oral ulcer) and the biomaterial (membrane) made by other chemical constituents, and tannic acid. The use of the term "carboxymethylcellulose" resulted in a patent, and that one is the same as the patent found in the USPTO database, that described the use of tannic acid in the treatment of soil.

European patent office (EPO) database

The patent informations in the EPO were obtained using the ESPACENET search tool, taking the Worldwide collection of patents as a reference. The search resulted in 2319 patents using the term "tannic acid" (Table 1). The five patents found with the combination of the term "tannic acid" and "healing" are the same ones available in WIPO database. This is because the World wide database provides access to applications from more than 90 countries. Using the words "tannic acid" and "wound" the study got a number of 17 patents. Among these, nine patents were related to the human needs and hygiene. For example, the preparation of a biomaterial (in the form
of powder or film) for wound treatment (George, 1970). The term "wound" was used in the abstract of four patents with no topical wound healing purposes. These patents included inventions related to textile and paper industry. The search for tannic acid and carboxymethylcellulose compositions resulted in 13 patents with different application areas, like anti-rust coating, hair dye, explosives, cigarette filter and drug entrainment.

**DERWENTS database**

In this database, 2926 patents were found using only the term "tannic acid" (Table 1). In addition to A61K classification, the C09D IPC also exceeded in number of
The C09D category belongs to the Chemistry and Metallurgy section, but specifically, to the class of coatings, inks, dyes and removers. The chemical field showed the greatest number of patents, followed by Polymer Sciences and Pharmacy (Figure 6). After analyzing the patent abstracts with the key words "tannic acid and healing", it was found that four patents used the term healing as a cure synonymous, causing results of curing agents, known as hardeners and used in Chemical, Polymer and Material Science sectors. Thus, only 27 patents were directly related to wound healing. Chen and Zhou (2014), proposed a formulation based on...
protease enzyme isolated from the terrestrial fungus Aspergillus and tannic acid, for the treatment of wounds originating from burns, chronic ulcers and diabetic foot. McClure (2001), has developed a pharmaceutical mixture which included sulfur, zinc oxide, tannic acid and olive oil to heal horses' wounds. According to the author, the product can be used in dogs, human beings, cows and administered topically as an ointment. The combination of the terms "tannic acid" and "carboxymethyl cellulose" resulted in 60 patents with different applications, as in the paint sector and drug delivery systems. Among the patents related to wound healing, there was a composition to treat burns which included menthol, thymol, camphor, vitamin E, tannic acid, niacin, Salvia extract and other constituents (Li and Zhang, 2014). Zhao (2013), developed a product constituted by seed extracts, fruit or bark, alcohol, glycerol, Carbopol, tannic acid, carboxymethyl cellulose and others. The paste obtained was indicated for the treatment of exudative ulcers, burns, eczema, bedsores and haemorrhoids.

Web of science database

The main collection of web of science is a tool that lets you search for various types of scientific papers (articles, patents, book chapters, etc.). The search resulted in on included 3460 documents that had "tannic acid" as a keyword, among which, 3080 were articles and two were book chapters. The United States was the country that had the largest number of research results developed with tannic acid (614 published articles), followed by India, Japan and China with 299, 298 and 246 articles, in that order (Figure 7). Brazil appears on the list with 97 publications, representing a significant number compared with patent applications. The publication period comprised the years 1960 (two posts) and 2014 (190 articles). Until the research data, it has published 35 articles in 2015. There is increasing interest in research that include to unravel the tannic acid properties aimed at different technological applications. Figure 8 shows the evolution of the number of publications per year. The chemical field presented the greatest number of publications with 595 articles (Figure 9). Among these articles, there is a study of processing and characterization of chitosan nanocomposites reinforced with chitin, using tannic acid as a crosslinking agent. The addition of chitin improved mechanical properties of the chitosan film and, tannic acid reduced the moisture content and solubility in water of these nanocomposites (Rubentheren et al., 2015).

The search for data with the combination of the terms "tannic acid" and "healing" resulted in 15 documents. Among these are 11 articles, six of which publications...
belong to the areas of Pharmacy and Chemistry, with three items each. Japan stood out with three published articles Table 2. One of these articles had a study of calcium phosphates composites which included tannic acid in the composition. The material was intended to repair bone defects (Yoshikawa and Toda, 2000). The tannic
### Table 2. Published articles about the tannic acid incorporation in the healing process of skin wounds (Web of Science).

</table>
acid can be applied in the dentistry field for the complex dentin-pulp protection.

In the area of wound healing, the development of tannic acid/chitosan/pullulan composite showed potential applications as a curative, with antibacterial properties against Gram-negative bacteria (*Escherichia coli*), and favor the attachment of fibroblast cells and intercalary growth on the membrane, regenerating the skin (Xuet et al., 2015). The healing properties of tannins is attributed to its astringent action, promoting the elimination of water into cells, leading to contraction of the fibers by decreasing hemorrhage and facilitating healing.

Akiyama et al. (2001), investigated the tannins antibacterial action against *Staphylococcus aureus* and the effect of standard chemotherapy in combination with tannic acid. The results indicate that tannic acid can be a useful adjunctive agent for treating skin infections caused by *S. aureus*, becausetis tannin seems to act on the cell membranes of *S. aureus*. The β-lactam antibiotics had their antistaphyloccocal activity enhanced by the presence of tannic acid.

Park et al. (2006) and Jung et al. (2010), examined the effect of tannic acid on skin inflammation with a cell line of human keratinocytes (HaCaT). Topical application of tannins in mouse skin treated with UVB irradiation demonstrated inhibition of erythema formation. The results showed that the tannic acid presented significant anti-inflammatory activity in response induced by UVB radiation on the skin and can be a natural candidate compound for regulating skin inflammation.

The combination of the words "tannic acid" and "wound" were found in 26 documents, including 23 articles. The United States published five articles, followed by Romania with 4 articles. Four of the 23 articles belong to the dermatological field, one of which evaluated the effects of burn treatment with highly purified tannic acid. The results indicate that purified tannic acid can provide a valuable tool for improving wound healing (Halkes et al., 2002). In another study, tannic acid promoted the stabilization of the collagen matrix against collagenolytic degradation, achieving significant results on wound healing in rats. The collagen-based material and tannic acid were considered biodegradable, and may have applications in tissue engineering and drug entainment (Natarajan et al., 2013). The tannic acid has important properties that gives it a variety of technological applications, especially in the Pharmaceutical field as curative in the wound healing process.

Using the "carboxymethylcellulose" and "tannic acid" terms, six articles were obtained of which covered different areas, such as quantification of heavy metals in water (Sui et al., 2013), substrates for isolated yeasts from the rotten wood (Middelhoven, 2006), wax additives (Tascioglu and Akar, 2003) and reduced astringency of phenolic compounds (Troszynska et al., 2010). Two articles have dealt with the use of tannic acid and carboxymethylcellulose as biomaterials in the medical

The LBL type of film prepared with tannic acid and AGNPS-Lis showed antioxidant and antibacterial activity and potential for application in food packaging, wound healing and tissue engineering.

Development of curative systems for wounds from nanocomposites of tannic acid/chitosan/pullulan. The material showed antibacterial properties and promoted the regeneration of skin on wound healing assays.

The quercetin, rutin, catechin and tannic acid were identified in the extracts of the leaves and bark of *Fraxinus angustifolia* species. The application of the extracts in wound healing promoted the cure of the wounds.
field. Shutava et al. (2009), research involved the development of nanocapsules with polyelectrolyte polymer for entainment of natural polyphenols, in order to assess its anti-cancer potential. The second article encompassed the studies by Aelenei et al. (2009), which reviewed the addition of tannic acid in biodegradable polyelectrolyte complex for medical and pharmaceutical applications. The results confirmed the possibility of adding tannic acid in microparticles based on chitosan, sodium alginate and carboxymethylcellulose. These complexes have shown potential for use in the treatment of dental pain and skin lesions. Table 2 includes the searches with tannic acid, pure or extract, in the development of biomaterials for the treatment of dermal healing.

Conclusion

In pure form or in extracts, the tannic acid introduced itself as a versatile material with applications in different industrial sectors. Regarding the healing subject, the United States, Japan and China are the countries that invested the most in the elucidation of mechanisms and inventions that contemplated the different properties of tannic acid in wound healing, burns and inflammations. Tannins are found in nearly all plant families, and Brazil has a large plant diversity, which makes it a potential field to develop biomaterials with extracts rich in tannic acid. The public spending on curative for skin ulcers is growing, which requires urgent researches to develop more effective healing systems at lower cost. Within this scenario, the tannic acid appears with potential application in topical formulations, although there are controversial ideas about its cytotoxic effects. Also, in Brazil the development of this economic sector is still lacking in research and technology.

Conflict of Interest

The authors have not declared any conflict of interest.

Received 14 July, 2014; Accepted 17 March, 2015

This study aims to investigate rice open field burning and their deleterious effects which has become an obvious problem in Egypt, which apparently affects the Egyptians’ lungs and increased hospital admission for pulmonary complaints. Therefore, this study was designed to investigate this phenomenon by using guinea pigs which were subjected to rice straws burning products (RSBP). The effects of RSBP on differential leukocytic count in lung lavages, histopathological examination, malondialdehyde (MDA) content in lung tissues (marker of lipid peroxidation) and nitric oxide (NO) content in lung tissues were studied. Results of this study demonstrated that RSBP induced pulmonary emphysematous lesions are progressive with subsequent smoke exposures together with the sensitization of the lung in the present model. Changes in the count of macrophages, neutrophils and eosinophils in the bronchoalveolar lavage (BAL) of guinea pigs lungs compared to normal lavages. RSBP exposure has a potent potential capacity for being a source of reactive oxygen species and possibly oxidizing species which can lead to decrease nitric oxide content in lung tissue.

Key words: Rice, straws, smoke, guinea pigs, total leukocytic count, neutrophil and eosinophils count, macrophages count, nitric oxide content, malondialdehyde content, lung, histopathological examination.

INTRODUCTION

Over the last few years, Egyptian farmers in the middle delta tend to burn the rice straw in the rice field as an easy and cheap method for its disposal. At the same time, farmers burn the rice straws to kill insects and provide minerals to the soil (Estrellan et al., 2010). Agricultural field burning activities are linked to elevated air pollution levels in Asia, for example, Taiwan (Yang et al., 2006), Thailand (Tipayarom et al., 2007), USA (Jiminez et al., 2007) and Europe (Viana et al., 2008). Clinicians working in agricultural areas in delta counties are aware of an abrupt increase of patients suffering from asthmatic attacks after the harvesting is completed, and the remaining paddy straws have dried up. The patients themselves are aware that rice smokes aggravate their airway symptoms after the harvesting season (from September to November) every year. This can result in adverse health effects (Regalado et al., 2006; Yang et al., 2007; Ryu et al., 2007).

In recent years, it has been observed that open burning of crop residues also contributes to emissions of harmful
air pollutants, which can cause severe impacts on human health, including polycyclic aromatic hydrocarbons (PAHs) (Korenaga et al., 2001), as well as polychlorinated dibenzo-p-dioxins (PCDDs), and polychlorinated dibenzofurans (PCDFs), referred to as dioxins (Gullett and Touati, 2003; Lin et al., 2007). These air pollutants have significant toxicological properties and are notably potential carcinogens. Air pollution not only affects human health and the environment, but also indirectly the economy of a country. Air pollutants and emission factors are considered for rice straw open burning. Open field burning is an uncontrolled combustion process during which species such as CO2, nitrous oxide (N2O), CH4, CO, non-methane hydrocarbons (NMHC), NOx, SO2, particulate matter (PM) and few others are being emitted as mentioned in Gadde et al. (2009) study. Among these, the greenhouse gases (GHGs) of importance are N2O and CH4 which contribute to global warming and climate change. CO2 emitted from biomass burning is considered to have a neutral effect due to its photosynthetic uptake during plant growth. Particulate matter (PM), because of their impacts on human health and the environment, can be further categorized as PM less than 2.5 micron (PM2.5) and PM less than10 micron (PM10). PAHs and PCDD/F are also of importance due to their toxicity and carcinogenic nature. Emission factors specific to air pollutant species emitted from open field burning of agricultural residues are presented in Gadde et al. (2009) study. This emission factors (EFs), which is the fraction of the mass combusted during the course of a fire, were collected from the literature and are mostly specific to rice straw burning.

A larger number of people can be subject to rice straws burning products (RSPB) effects in the event that the dominant winds are directed towards more densely populated areas since many urban areas are typically located next to rice cultivated areas. Therefore, although rice cultivation has assumed great importance for the national economy, especially because of the growing demand for food in the current decade, it presents a high potential for environmental impact. This burning practice is likely to remain an important issue until effective measures are taken to eliminate this practice. The rice smoke is an important PAH emission source. The rice straw burning primarily contributes fine particulate PAHs. During the rice straw burning periods, PAH size distribution shows that 70.9% of PAH mass is distributed in the sizes smaller than 2.5 mm, which can easily penetrate the pulmonary alveoli and damage the health of humans (Hsi-Hsien et al., 2006; Chia-Hsiang et al., 2009).

Particles from wood smoke have been associated with various indicators of inflammation, including pulmonary influx of inflammatory cells such as neutrophils, lymphocytes and alveolar macrophages (Larsson et al., 2007). An increase of neutrophils in the airway lumen has been documented by bronchoalveolar lavage (BAL) fluid and sputum analysis in smokers with mild to moderate chronic airway obstruction (Bohadana et al., 2004). The guinea pig cigarette smoke (CS) models have contributed to the understanding of histological and physiological aspects of smoke-associated lung disease. Guinea pig models are considered to be adequate for further investigations of chronic obstructive pulmonary disease (COPD) because of the anatomicaland pathophysiological similarities to human COPD. The guinea pig develops morphologic and physiologic alterations after exposure to cigarette smoke at roughly the same concentrations as humans. In contrast, rats and mice require respectively greater and shorter exposure concentrations before developing disease than humans do (Kubo et al., 2005; Ricciardolo et al., 2008).

In this study, we used guinea pig model for exposure to RSPB, and sensitization with egg albumin for simulation of hypersensitivity reaction, in order to investigate various histopathological changes and bronchoalveolar lavages to see what possible cells are responsible for lung damage. The suspected effects of the RSPB on the content of malondialdehyde (MDA) in lung tissues as a marker of lipid peroxidation, and oxidative stress have also been investigated. Nitric oxide (NO) content in lung tissues was also studied.

MATERIALS AND METHODS

Normal healthy male guinea pigs (Egyptian breeding) weighing 400 to 500 g were used. The animals were kept in cages, in a standard animal laboratory room. They had free access to water and food at room temperature. At the moment of experiment, guinea pigs were all of the same age, and had approximately the same body weight in order to minimize biological variations. Rice straws were brought from nearby country area in Gharbiya County, Tanta, Egypt. The burning rate was adjusted to burn about 10 g of rice straws in about 20 min on an electric heater (Gallenkamp Magnetic Stirrer Hotplate 400, UK). It was adjusted at the middle heat which was about 200°C. The burnings were continued for 4 h per day in a burning chamber. The animal exposure was performed by direct inhalation of the smokes for 4 h. Smokes comes out from burning chamber by inlet pipe to exposure chamber made of wood of the following diameters 90×50×45 Cm with inlet opening for air atmosphere to enter. The area of the pipe of the inlet is about (1 cm²) (Six animals per each exposure chamber).

Egg albumin suspension (EA)

A suspension of egg albumin (Sigma Chemical Co. Ltd., Egypt) was prepared in normal saline to give a final concentration of 100 mg/ml and 10 mg/ml for sensitization of guinea pigs.

Induction of sensitization

Guinea pigs sensitization was induced according to a previously described procedure (Mccalg, 1987). The animals were injected subcutaneously and intraperitoneally I.P. with two equal doses of egg albumin and 1 ml of suspension containing 100 mg egg albumin (EA) on day one, and a further 10 mg I.P. on day eight. At
day 14, sensitized animals were exposed to an aerosol of 4% EA for 18±1 days, 4 min daily. The aerosol was administered in a closed chamber, dimensions 30x20x20 cm. Control group was treated identically, except that 0.9% saline vehicle alone was used. The animals were ready for exposure to the RSBP.

**The experimental design**

The animals were divided into six groups. Six guinea pigs were used in each group:

A. Control group: Non-exposed normal guinea pig.
B. Egg albumin sensitization group: Guinea pigs with sensitized lungs.
C. Acute RSBP exposed group: Normal guinea pigs exposed to RSBP for two weeks.
D. Subchronic RSBP exposed group: Normal guinea pigs exposed to RSBP for four weeks.
E. Sensitized acute RSBP exposed group: Sensitized guinea pigs exposed to RSBP for four weeks directly after sensitization period.
F. Sensitized Subchronic RSBP exposed group: Sensitized guinea pigs exposed to RSBP for four weeks directly after sensitization period.

**Inflammatory cell analysis in bronchoalveolar lavage (BAL)**

Guinea pigs were anaesthetized with pentobarbital sodium (60 mg/kg, i.p.). The thorax was opened and the aorta and inferior vena cava were cut. The trachea was then cannulated and 10 ml of phosphate buffered saline at 37°C was gently introduced into the lung and then gently withdrawn. Three further washes with 10 ml of saline were carried out. The combined lavage fluid was kept in an ice bath. The collected BAL was centrifuged at 1,500 rpm for 10 min, (GIBCO, Grand Island, NY). Total cell counts were determined by using (Burkerhemocytometer, NY). Differential leukocyte counts were then performed on cytospin slides. A minimum of 300 cells were identified and differentiated as mononuclear cells, neutrophils or eosinophils using the standard morphological criteria (Kubo et al., 2005). Points falling on a specific cell type must be counted, and then divided by the total number of points falling on tissue area in each microscopic field, as previously described (Gundersen et al., 1988)

**Determination of lung lipid peroxides contents measured as malondialdehyde (MDA)**

MDA lung tissue content was assayed as an indirect indicator of in situ lipid peroxidation (Yoshioka et al., 1979). Briefly, lung tissues were homogenized in 10 volumes ice-cold 1.15% (w/v) potassium chloride solution using polytron homogenizer (PT 3100). To 0.5 ml of homogenate, 3 ml of 0.5% (w/v) trichloroacetic acid and 1 ml of 0.6% (w/v) thiobarbituric acid were added; the entrioresolution was then mixed and heated for 45 min in a boiling water bath. After cooling, 4 ml n-butanol was added and the sample vigorously shaken. The n-butanol layer was separated by centrifugation at 3000 rpm for 15 min. The absorbance of the pink colored product was measured at 535 nm against blank containing water instead of the sample, using double-beam spectrophotometer (Shimadzu UV-PC 1601, Japan).

**Determination of lung nitric oxide contents**

The lung nitric oxide content was determined by measuring its stable metabolites nitrate and nitrate (Miranda et al., 2001) briefly, lung tissues (= 0.25g/guinea pig) were homogenized in 10 volumes of ice cold saline (0.9% NaCl) using polytron homogenizer (PT3100). 1 ml absolute ethanol was added to 0.5 ml of the homogenate to precipitate proteins. Samples were centrifuged at 3000 rpm for 10 min. Addition of 0.5 ml saturated solution of vanadium (III) chloride (8 mgVCl3/ml) to 0.5 ml of the clear supernatant was rapidly done, followed by addition of 0.5 ml freshly prepared griess reagent. The mixture was vortexed, and incubated at 37°C for 30 min in a water bath. The absorbance of samples was measured at 540 nm using double-beam spectrophotometer (Shimadzu UV-PC 1601, Japan).

**Histopathological examination of lung sections**

At the end of the rice smoke exposure, the lungs were immediately removed, washed with saline, and prepared for histopathological examination. The lungs was immediately fixed in 10% buffered formalin solution (pH 7.4) for 24 h, and then routinely processed in ascending grades of alcohol, then xylene. The tissues were then embedded in paraffin wax, serially-sectioned to ≈ 4 μm thickness, and stained with Hematoxylin and Eosin (H&E; Sigma). Ultimately, each stained tissue section was examined using a light microscope (Olympus BX 51, Olympus America, Melville, NY) and photographed with a digital camera (Olympus DP11) connected to the microscope.

**Statistical analysis**

The results represented as the mean ± SD of cell count change. The collected data were organized, tabulated and statistically analyzed using SPSS software (Statistical Package for the Social Sciences, version 16, SPSS Inc. Chicago, IL, USA). For comparison between more than two means of parametric data, F value of ANOVA test was calculated, where scheffe test was performed to compare between each two means if F value was significant. Significance was adopted at p<0.05 for interpretation of results of tests of significance (Dawson and Trapp, 2001) (Tables 1 and 2, Figures 15 to 18)

**RESULTS AND DISCUSSION**

The resulting hazards of smoke exposure arise from burning of rice straws and its deleterious effects on the lungs of exposed persons in Egypt. Fine particles, one of the major pollutants emitted from the field burning of rice straws, are of major concern due to their harmful effects on human health (Pope et al., 2009). Crop rice burning is a serious environmental health hazard, and children are more sensitive to air pollution, as RSBP poses some unrecoverable influence on their pulmonary function test (PFT) (Awasthi et al., 2010), early small airway obstruction (Ravinder et al., 2012). PAHs compounds have also been reported to induce a release of pro-inflammatory mediators, supporting a role for PAHs in the pro-inflammatory response (Lecureur et al., 2005). Substituted PAHs, such as nitro- and o xo-PAHs, have been suggested to affect biological systems by induction of oxidative stress, mitochondrial damage, necrosis and apoptosis (Xia et al., 2004; Kubatova et al., 2006; Landvik et al., 2007).

*Significant (P<0.05)

Total WBC significantly increased in subchronic exposed groups with normal or sensitized lungs, also in sensitized acute exposed lungs which suggest that RSBP had the potential to alter host pulmonary immune defense mechanisms. However, gp B, which was sensitized and not exposed to RSBP, also had an increase of WBC, once sensitization is related to inflammation. So, cell recruitment observed in groups E and F could have happened in response to both sensitization and RSBP exposure.

In the present study, non exposed Egg albumin sensitized lungs (gp B), acute normal RSBP exposed (gp C), (gpE) acute RSBP sensitized and subchronic RSBP sensitized (gp F) exposed lungs show significant decrease in macrophages count compared to control non exposed group. This may be explained by another study of Nieuwenuhuzen et al. (2012) who demonstrated that macrophages are not necessary for allergic airway disease, and may only be a consequence of the elevated T helper t-lymphocytes (Th2) response. They studied the contribution of macrophages to acute, chronic and house-dust-mite-induced allergic airway inflammation by using mice with abrogated IL-4Rα signaling on macrophages. It was demonstrated that airway hyperreactivity, Th2 responses, mucus hypersecretion, number of eosinophils, and collagen deposition were not significantly affected by decreased development of macrophages. Also, macrophages seem to be beneficial to the resolution of asthma through production of IL-10 but are not present or not functional in asthma, and therefore allergic inflammation can progress (Fitzpatrick et al., 2010). This of course is in line with the above-cited finding by Shaykhiev et al. (2009) that macrophages genes are down regulated in alveolar macrophages of healthy smokers and smoking COPD patients as compared to nonsmokers.

It has been noticed that the increase of Neutro-
phils count occurred not only in RSBP groups (D, E, F), but also in Group B (Sensitized only) compared to control non exposed (gp A). This suggests that the sensitization of the lungs and exposure of RSBP for two or four weeks induce proliferation of neutrophills and infiltration in the lung. Also, we found a close association of neutrophil infiltration with emphysematous changes, and destruction of alveolar walls (Figures 1- 9). These findings indicate that the protease-antiprotease imbalance had already occurred in exposure model. In
other studies, an increase of neutrophils in the airway lumen has been documented by bronchoalveolar (BAL) fluid and sputum analysis in smokers with mild to moderate chronic airway obstruction (Bohadana et al., 2004), and a good correlation was observed between the number of neutrophils and the annual decline in forced
expiratory volume in the first second (FEV1) (Bohadana et al., 2004; Ravinder et al., 2012).

It has been noticed that eosinophils was not present in the BAL of control (gpA). It has been noticed that the increase of eosinophils count occurred in sensitized groups exposed or not. The significant increase was only present in sub chronic exposure of RSBP (gpF) compared to nonexposed sensitized group (gpB). Airway inflammation with eosinophilic infiltration of the bronchial mucosa is a characteristic feature of atopic asthma (Akuthota et al., 2011). It have been found that stimulation ofmacrophages by ovalbumin uptake induced increased production of IL-10 by these macrophages which could play an important role in the resolution of asthma (Fitzpatrick et al., 2010), and this resulted in lower levels of IL-5 and ovalbumin-specific IgE, and a lower number of eosinophils in a mouse model of asthma (Vissers et al., 2004).

It has been reported that rice straws, and its smoke up regulate the expression of intercellular adhesion molecule-1 (ICAM-1) and human leucocyte antigen (HLA) on Eosinophils which play an important role in Eosinophils function, migration and degranulation (Kayaba et al., 2004). Eosinophils may also contribute to the induction of airway remodelling by synthesizing a variety of profibrotic mediators. Eosinophils are thought to be an important source of the potent pro-fibrotic cytokine TGF-β (Cho et al., 2004). TGF-β is able to induce extracellular matrix (ECM) protein production (Kenyon et al., 2003), and also contributes to the accumulation of fibroblasts below the reticular basement membrane by stimulating fibroblast proliferation. It further contributes to airway remodelling by promoting the differentiation of myofibroblasts from resident fibroblasts, and also from circulating precursor cells known as fibrocytes (Mori et al., 2005). The differentiation of myofibroblasts into smooth muscle cells (Wicks et al., 2006), and their proliferation (McMillan et al., 2005) may also be governed by TGF-β. This was confirmed by histopathological examination of lungs sample of subchronic sensitized RSBP exposed group (gpF) showed pericatricial emphysema with interstitial fibrosis in three animals out of six (Figure 12). In the present study, it has been noticed that basophiles wasn’t present in the BAL of all groups except in acute and subchronic RSBP exposed sensitized lungs with no significant changes. Histopathological examination of lungs sample of acute RSBP exposed group (gp C) showed mild to moderate thickened interalveolar septa (mild edema and minimal infiltrated) together with mild to moderate peribronchial mononuclear cellular infiltrations with normal empty alveolar spaces in four animals (Figure 5), and the two remaining animal showed the same findings associated with intraalveolar cellular exudates (Figure 6). These findings are compatible with previous study (Li et al., 2003).

Histopathological examination of lungs sample of subchronic RSBP showed the result of exposed group (gp D). Another two animals showed diffuse thickening of
Figure 6. Lung section of guinea pig with normal lung aspirated RSBP for two weeks (gp C) showing mild to moderate thickened interalveolar septa (arrow head) (mild oedema & minimal infiltrated) together with mild to moderate peribronchial mononuclear cellular infiltrations with normal empty alveolar spaces with intraalveolar cellular exudates (star) (in two guinea pigs out of six) (H&E ×125).

Figure 7. Lung section of guinea pig with normal lung aspirated RSBP for four weeks (gp D) showing moderate mononuclear interstitial & peribronchial mononuclear cellular infiltration associated with interalveolar cellular debris (arrow head) with focal areas of destroyed interalveolar septa (emphysematous spaces) (star) (in two guinea pigs out of six) (H&E ×125).
Figure 8. Lung section of guinea pig with normal lung aspirated RSBP for four weeks (gp D) showing showed diffuse thickening of interalveolar septa with mononuclear cellular infiltration around blood vessels and bronchioles (star) with patchy emphysematous spaces (arrow head) (in two guinea pigs out of six) (H&E ×125).

Figure 9. Lung section of guinea pig with normal lung aspirated RSBP for four weeks (gp D) showing peribronchial focal micronodular mononuclear cellular accumulates (arrow head) (in two guinea pigs out of six) (H&E ×125).

interalveolar septa with mononuclear cellular infiltrations around blood vessels and bronchioles with patchy emphysematous spaces (Figure 8), and the last two animals showed peribronchial focal micronodular mononuclear cellular accumulates (Figure 9). These findings are compatible with previous studies (Li et al.,
Histopathological examination of lungs sample of sensitized acute RSBP exposed group (gp E). The remaining two animals showed the typical picture of interstitials pneumonia (interstitial mononuclear cellular infiltration with the presence of some hyalinized bodies), dilated arterioles and perivascular edema (Figure 11). Histopathological examination of lungs sample of sensitized acute RSBP showed the result of exposed group (gp E). The remaining two animals showed the typical picture of interstitials pneumonia (interstitial mononuclear cellular infiltration with the presence of some hyalinized bodies), dilated arterioles and perivascular edema (Figure 11). Histopathological examination of lungs sample of sensitized acute RSBP exposed group (gp E) showed interstitial mononuclear cellular infiltration with numerous cellular nodules with large wild emphysematous spaces in four animals (Figure 10).
lungs sample of sensitized subchronic RSBP exposed group (gp F) showed pericatricial emphysema with interstitial fibrosis in three animals (Figure 12). Histopathological examination using H&E stain of lungs sample of sensitized subchronic RSBP exposed group (gp F). The remaining three animals showed dense interalveolar inflammatory infiltration hyperplastic bronchial epithelium with peribronchial inflammatory infiltration with peribronchial emphysematous bolea formation (Figure 13). These findings are compatible
Figure 14. Mean values of malondialdehyde (MDA) and nitric oxide content (NO) of the study groups of guinea pigs (exposed and not exposed to rice straw burning products (RSBPs) (n=36). Group A: control group, group B: Egg albumin sensitization group, group C: Acute RSBP exposed group, group D: Subchronic RSBP exposed group, group E: Sensitized acute RSBP Exposed group, group F: Sensitized Subchronic RSBP exposed group. Results expressed as the mean of MDA content (µM/g tissue) ± SD; n = 6/group. The mean value was significantly different between GA and GD (normal lungs) at p < 0.05. The mean value was significantly different between GB and GE, GF (sensitized lungs) at p < 0.05.

Figure 15. Mean values of total white blood cells (TWBCs) of the study groups of guinea pigs (exposed and not exposed to rice straw burning products (RSBPs) (n=36). Group A: control group, group B: Egg albumin sensitization group, group C: Acute RSBP exposed group, group D: Subchronic RSBP exposed group, group E: Sensitized acute RSBP Exposed group, group F: Sensitized Subchronic RSBP exposed group. Results expressed as the mean of total leukocytic count (cell/µm²) ± SD; n = 6/group. The mean value was significantly different between GA and GD (normal lungs) at p < 0.05. The mean value was significantly different between GB and GE, GF (sensitized lungs) at p < 0.05.
Figure 16. Mean values of macrophages of the study groups of guinea pigs (exposed and not exposed to rice straw burning products (RSBPs) (n=36). Group A: control group, group B: Egg albumin sensitization group, group C: Acute RSBP exposed group, group D: Subchronic RSBP exposed group, group E: Sensitized acute RSBP Exposed group, group F: Sensitized Subchronic RSBP exposed group. Results expressed as the mean of macrophages count (cell/um²) ± SD; n = 6/group. The mean value was significantly different between GA and GC (normal lungs) at p < 0.05.

Figure 17. Mean values of neutrophils of the study groups of guinea pigs (exposed and not exposed to rice straw burning products (RSBPs) (n=36). Group A: control group, group B: Egg albumin sensitization group, group C: Acute RSBP exposed group, group D: Subchronic RSBP exposed group, group E: Sensitized acute RSBP Exposed group, group F: Sensitized Subchronic RSBP exposed group. Results expressed as the mean of neutrophils count (cell/um²) ± SD; n = 6/group. The mean value was significantly different between GA and GD (normal lungs) at p < 0.05. The mean value was significantly different between GB and GE, GF (sensitized lungs) at p < 0.05.

Malondialdehyde (MDA) is the end product of lipid peroxidation, and an indicator of oxidative stress (Kamal et al., 1989). Antioxidant enzymes such as superoxide dismutase (SOD) and glutathione peroxidase (GSH-Px) are essential for preservation of cellular balance and...
elimination of free radicals (McLaughlin et al., 1990). The present results have shown that there was significant increase in the level of MDA in the lung tissues in (D, E, F) groups that had been exposed to the smoke of RSBP in normal or sensitized lungs. These results suggest that the RSBP exposure has a potent potential capacity for being a source of reactive oxygen species and possibly oxidizing species. Confirmatory observation by Ho and Kou (2002) who reported the increase hydroxyl radical (OH) burdens following smoke exposure which was actively involved in evoking the acute irritant effects of wood smoke. Oxidative stress has been shown to be an important contributor to the pathogenesis of COPD (Ito et al., 2009).

It has been demonstrated in the present study that the concentration of nitric oxide (NO) contents showed a significant increase in the normal group than in other RSBP exposed groups. It have been reported that NO, was significantly decreased in cigarette smoke-exposed animals compared with healthy controls (Pekmez et al., 2010). It is quite possible that RSBP exposure was interfered with the function of endothelial nitric oxide synthase (eNOS). This was supported by the observation of MacNee (2000) who reported that smokers have serum and tissue evidence of oxidative damage to many proteins like tetrahydrobiopterin (BH4), a required cofactor for eNOS activity, which can be altered to its inactive BH2 form by oxidants, and in this situation switches production from NO to superoxide (O\textsuperscript{2-}) (Heitzer et al., 2000; Wagnner et al., 2007). Peroxynitrite, a highly reactive molecule, is produced in a near diffusion-limited rate as a reaction between O\textsuperscript{2-} and NO. Peroxynitrite can oxidatively inactivate eNOS, thus decreasing NO synthesis, and in addition peroxynitrite catalytically disrupts eNOS, resulting in increased O\textsuperscript{2-} production by the eNOS dimers (Zou et al., 2004).

Furthermore, cigarette smoke has been shown to inhibit production of tetrahydrobiopterin (Heitzer et al., 2000), disrupt the active eNOS dimers, and abnormally phosphorylate eNOS, producing an inhibitory state, all of which are alterations that would reduce NO bioavailability (Wagnner et al., 2007). Smoke also exerts a number of other effects on eNOS production. TNF\textalpha which is increased in the sputum of human smokers with chronic obstructive pulmonary disease (COPD) and in the plasma of animal models of COPD (Churg et al., 2002), destabilizes eNOS mRNA (Neumann et al., 2004; Searles. 2006). Smoke also contains large concentrations of O\textsuperscript{2-} which can reduce functional levels of NO by converting it to peroxynitrite (Wright and Churg, 2008).

**CONCLUSION**

This study has demonstrated that RSBP induced pulmonary emphysematous lesions are progressive with subsequent smoke exposures together with the sensit-
zation of the lung in the present model. RSBP have the ability to change the counting of macrophages, neutrophils, eosinophils in the BAL of guinea pigs lungs compared to normal lavages. RSBP exposure has a potent potential capacity for being a source of reactive oxygen species and possibly oxidizing species which can lead to decrease nitric oxide content in lung tissue. It was found out that Rice straws burning products can easily penetrate the pulmonary alveoli and damage the health of humans. It is recommended that the rice burning activities should be stopped as it affects human health, and we should find alternative ways for disposal of the rice after harvesting.

Received 20 October, 2014; Accepted 29 June, 2015

Tree nuts and their products are highly nutritive and beneficial to health. On the other hand, some of them can lead to development of allergic reactions, protein intolerance or liver diseases in some groups of consumers. Therefore, it is important to study the risks of tree nuts ingestion as a major issue for food regulators and the pharmaceutical industry safety. A review of surveillance and correlation to possible Brazil nut allergy reactions with effects on consumers and some therapeutic potential was carried out to help in understanding the mechanisms and so preventing damages to sensitive consumer’s health.

Key words: Bertholletia excelsa, aflatoxin, allergy, protein, immunoglobulin, risk.

INTRODUCTION

Allergies

Adverse reactions caused by the consumption of some foods have been widely studied and reported since ancient times. They can occur by several mechanisms. However, the food allergies are caused by specific immune responses (immune mediated). Food allergy is defined as an immune response to food proteins disease (Cianferoni and Spergel, 2009). For example, in the urticaria (commonly referred to as hives) the symptoms and the anaphylaxis are triggered by the immunoglobulin E (IgE), which is antibody-mediated immune responses. On the other hand, the cell-mediated diseases (eosinophilic esophagitis and enterocolitis), which are also induced by food proteins, are classified as Mixed IgE and No-IgE mediated. The allergic reactions involve immunologic mechanisms that may or may not be mediated by the IgE. They are usually associated to food allergies and hypersensitivity reactions characterized by a rapid release of mediators such as histamine (Figure 1).

On the other hand, the term food intolerance (non-immune mediated) refers to any abnormal response to (one or more than one) specific food, food substance (lactose/caffeine/fish proteins) or additive (sulfites) without the involvement of immunologic mechanisms. Allergies are characterized by the IgE synthesis against antigens that enter the body through ingestion, the inhalation (particles) or dermis contact (skin). Food allergy is an increasingly common problem in Western countries, and an effective therapeutic treatment is needed, however, it has not been
accomplished yet. Some therapeutic strategies have been investigated to identify the foods that most often cause severe anaphylactic IgE-mediated reactions, which commonly cause allergies in children (such as peanuts, walnuts, and shellfish or cow's milk and hen's egg). Boyce et al. (2010) strategies stated that an adverse reaction to food may be: (a) a mediated-immune response: food allergy (food protein-induced and urticaria reactions) or celiac disease; and (b) non-mediated-immune response: primary food intolerance (lactose, caffeine, histamine, and sulfite intolerance).

Food allergy should be considered in individuals presenting anaphylaxis or any combination of symptoms that occur: within minutes to hours of ingesting food (especially in children) or after the ingestion of a specific food (on more than one occasion). The severity of allergic reactions to foods, however, is multifactorial and variable. Accordingly, the approaches being pursued are both food allergen-specific and -nonspecific. The allergen-specific approaches include oral, sublingual, and epicutaneous immunotherapy. It is carried out with native food allergens and mutated recombinant proteins. Diets containing cooked foods (milk and eggs) are an alternative approach to food oral immunotherapy and are already changing the paradigm of strict dietary avoidance for patients with food allergy. On the other hand, the nonspecific approaches include monoclonal anti-IgE antibodies, which might increase the threshold doses for food allergen in patients with food allergy. The variety of strategies for the treatment of food allergies increases the likelihood of success. Schreier and Wright (2014) reported that it is also necessary to consider, among the risk factors, the environmental influences on the healthy development of an immune system (during critical stages of development), particularly in the intestine. It is also important to mention that in addition to genetic predisposition, the psychological stress is known to play an important role in allergic and other inflammatory diseases, such as asthma.

Food additives such as sulfites (asthma), monosodium-glutamate and tartrazine (hives) and other chemical substances that are added to foods are also associated with adverse reactions (ASBAI, 2008). Regarding environmental aspects, the presence of mycotoxins (carcinogens that are products of fungal metabolic processes - immune systems suppressors) in the environment can be considered as a factor that increases the immune response. A family history of atopy and the presence of atopic dermatitis is already considered risk factors for sensitization to food allergens and the development of food allergy. According to Schutze et al. (2010), epidemiological studies have shown that indoor fungi, including mycotoxin producers, are associated with increased prevalence and exacerbation of respiratory diseases. Low et al. (2011) reported that the environmental growth conditions significantly influence the allergenicity of common fungi (through the differential production of allergenic proteins), and they highlight the importance of allergenicity measurements for understanding the environmental exposure to allergenic fungi. Still considering the environmental exposure, cross-reactivity may occur due to the presence of aeroallergens.

According to Souza and Rosario Filho (2012), house dust mites are the main sensitizers of atopic individuals, followed by cockroaches (Periplaneta americana and Blattella germanica), which caused skin reactions in 24.1% of people with asthma. Bees (Hymenoptera) can also cause anaphylactic reactions. According to Kohler et al. (2014) the diagnosis of allergy by bee stings is usually based on clinical history of anaphylactic reactions. The antibodies cross-reactive to conserve structures found in allergens include homologous primary structures of protein allergens (Hyaluronidases, Dipeptidyl peptidases IV and Vitelloigenins) and cross-reactive carbohydrate determinants that are present in the majority of Hymenoptera venoms. Regarding
The allergic reactions to tree nuts are a growing global phenomenon. Mast cell complexes are cross linked, leading to cell activation and release of pro-inflammatory mediators. IgE mediated reaction involves IgE receptors on mast cells and basophils. When allergen is reintroduced, these M-IgE/FcεRI complexes are crosslinked, leading to cell activation and release of pro-inflammatory mediators (Otsu and Dreskin, 2011).

**Food allergy x tree nuts**

The allergic reactions to tree nuts are a growing global issue...
functions: (a) Allergens: enzymes (mainly proteases), belonging to protein families with diverse biological allergic reaction. The substances that cause food allergy are generally difficult to isolate and purify, triggering hypertension (Alexiadou and Katsilambros, 2011; facts that they reduce blood pressure and the risk of their benefits to the cardiovascular system and to the specific populations. They stand out especially due to part of the diet of some consumer groups and of nutritional compounds and antioxidant activity and a re.

Some tree nuts have been studied for the bioaccessibility with a higher prevalence of causes of food allergies. specific foods such as tree nuts, commonly associated between clinical reports and the consumption of foods. Nut allergy can be dangerous and that it may occur in highly atopic individuals of any age with a strong family history of atopy (Ridout et al., 2006). The prevalence of tree nut allergy in the United States of America (USA) in children is about 0.5% (Boyce et al., 2010). In Brazil, Guimarães et al. (2015) collected information from parents of pre-school children with allergy to different foods and found the following: milk (42.7%), pork (11.6%), fruits (10.9%), chocolate (9.4%), and eggs (9.2%). Investigating the prevalence of sensitivity to food allergens in children in Brazil, Naspitz et al. (2004) reported reaction to food allergens in subjects tested for IgE sensitivity, indicating a significantly greater proportion of sensitive individuals than non-sensitive ones.

Table 3 shows the prevalence of tree nuts allergy in patients from several countries. Unfortunately, there is still little information on the prevalence and incidence of food allergy in developing and emerging economies such as China, India, and Brazil. Brazil nut (Bertholletia excelsa HBK), for example, a seed native to the Amazon region, has remarkable nutritional properties, especially the contents of protein and sulfur amino acids. However, the nutrient profile of tree nuts is associated to allergic reactions. Nut allergy can be dangerous and that it may occur in highly atopic individuals of any age with a strong family history of atopy (Ridout et al., 2006). The nutritional and therapeutic potential of tree nuts and the pathology and immune reactions that influence the inherent risks associated with their consumption need to be evaluated. In order to discuss the case-reports of Brazil nut allergy this review is presented.

Brazil nut and allergy reactions

Composition

Brazil nut is an extractive product of the Amazon region, that is, the fruits are collected from the forest when they fall freely from the trees to the ground during the rainy season and from which the seeds are removed and industrially processed. It can be used as raw material for the production of various products. Its worldwide

production is of 78,000 tones (Freitas-Silva and Venâncio, 2011). It is an excellent source of proteins, carbohydrates, lipids, vitamins, and minerals. Its lipid content is over 60%, and the ratio of saturated, monounsaturated and polyunsaturated fatty acids is 25:41:34 (USDA, 2008). It is a source of vitamin E and sulfur amino acids. Among which, methionine and cysteine are part of the 2S albumin protein fraction, the most relevant protein fraction in Brazil nuts, which makes it more appealing than other nuts that lack sulfur amino acids, essential to human health. Brazil nut is also a source of micronutrients such as selenium (Se), phytosterols, tocopherols, squalene and phenolic compounds (Costa et al., 2010; Silva et al., 2010). Beta- and gamma-tocopherols are the most abundant tocopherol isomers present in Brazil nuts. Barium (Ba) and Radio (Ra) can also be found in Brazil nuts (Martins et al., 2012).

Compared to other tree nuts, Brazil nuts are known as the best source of Se (Pacheco and Scussel, 2007; Chunhieng et al., 2008; Manfio et al., 2012). Adequate intake of Se is essential for normal activity of Se-enzymes involved in the protection against oxidative stress, maintenance of the redox system, modulating the immune system, and regulation of the thyroid. Thomson et al. (2008) demonstrated that 100 µg/day of Se (equivalent to two units of Brazil nuts) ingestion for three months was effective on increasing plasma Se concentrations and glutathione peroxidase in healthy individuals. Stockler-Pinto et al. (2010) reported that the ingestion of a single serving of Brazil nut (5 g) a day for three months is effective in increasing the concentration of Se and glutathione peroxidase activity in patients with Se deficiency improving the antioxidant capacity of this mineral. Accordingly, the association between Se content and amino acids in Brazil nuts has been investigated. Silva et al. (2010) reported that Brazil nut showed the organic species se-methionine and Se-cystine after water extraction, but after simulated gastrointestinal digestion, only Se-methionine was found as bio accessible, corresponding to 74% of total Se (54.87 ± 4.6 µg/g). Analysis of urine samples suggested the

Presence of Se-cystine, and there were no significant differences between samples from men and women in terms of the concentration of this species after consumption of Brazil nuts (1 nut/day for 15 d). Therefore, food processing appears to influence the potential allergenicity associated with the protein fraction. According to Van Boxtel et al. (2008), in Brazil nuts, for example, the protein fraction 2S albumin (denominated Ber e1), considered the major allergen, was stable to in vitro peptic digestion. Thermal denaturation (melting) can affect the digestibility of protein, since these authors found that the denaturation temperature of 2S albumin ranged from 80 to 110°C, depending on the pH value.

Under heating at temperature higher than its denaturation temperature, at pH 7.0, there was partial formation of insoluble protein aggregates and the protein dissociated into its polypeptides, while heating at pH 5.0 did not seem to induce aggregation or dissociation of protein aggregates. The denaturation temperature of about 110°C, under pH values corresponding to the general food pH values (pH 5 to 7) is high. As a result, it is likely that heat processing causes the denaturation of allergy protein fraction present in food products. Koppelman et al. (2005) investigated the high resistance of 2S albumin fraction, previously identified as an allergen, against proteolysis by pepsin. They found that although the protein denaturation temperature exceeds 110°C, at neutral pH, a fully reversible thermal denaturation was observed at 82°C at low pH. Chemical processing (the subsequent reduction and alkylation of the protein) was used to destabilize the globular fold. Far-UV circular

dichroism and infrared spectroscopy showed that the reduced and alkylated form lost some structures, whereas the alpha-helix structure of protein was protected. Accordingly, studies on protein digestion are important due to the potential allergenicity of Brazil nut 2S albumin.

Protein versus Brazil nut allergy

Since ingestion of some proteins is associated with allergic reactions in some consumers, Breiteneder and Mills (2005) summarized the common biochemical and physicochemical properties of food allergens. They reported that thermal stability, resistance to proteolysis, binding capacity, and lipids interactions are factors that promote the allergenic properties of food proteins. Although one or more of these factors are characteristic of the allergen proteins, there is no rule to predict the allergenicity of a given protein. It is well known that proteins denature under high pressure. Thus, several attempts have been made to change the structure of the protein allergens using high pressure processing in order to reduce its allergenicity. Several studies have been carried out on simple protein solutions and on complex food systems. Allergens have been investigated under or after high-pressure treatment using methods capable of detecting changes in the secondary and tertiary structures of proteins. When considering the protein content of the Brazil nut as potentially high (13-19 g%) and its essential amino acids, the beneficial aspects should be highlighted without disregarding food allergies. Table 4 presents the contents of protein and amino acids, including the sulfur amino acids.

In Brazil nut the methionine content is higher than cashew and peanut, and the amount of sulfur fraction has been studied in allergic reactions. Sun et al. (1987) studied the protein fractions (11S, 7S, and 2S) and registered that they contain high concentrations of glutamine/glutamic acid and arginine. However, the 2S protein contains unusually large amounts of sulfur amino acids (17.9% methionine and 8.7% cysteine). The major allergens found in Brazil nut are: (a) 2S albumin and (b) 11S legumin (Ber e 2) (Crespo et al., 2006). According to Van Bilsen et al. (2013), it is not known exactly why certain food proteins are more likely to cause reactions. One of the characteristics of most food allergens is that they are stable to the acidic and proteolytic conditions in the digestive tract. This property appears to be a risk factor for allergic sensitization. Van Bilsen et al. (2013) investigated the contribution of 2S albumin protein structure to the ability to induce in vivo oral sensitization using an animal model of food allergy. Disulfide bridges of albumin 2S were reduced and alkylated resulting in loss of protein structure and an increased in vitro pepsin digestibility. The reduced and alkylated

1 years old; 2 IgE Skin-prick tests in response to extracts of Brazil nut and positive radioallergosorbent tests; 3 not applicable; 4 Not informed; 5 United States of America; 6 IgE measurement; 7 United Kingdom; 8 amount of Brazil nut ingested; 9 male & female.

Forms of 2S albumin were administered by daily gavage dosing of 0.1 and 1 mg to rats for 42 days. Intraperitoneal administration was used as a positive control.

The enzyme-linked immunosorbent assay (ELISA) and passive cutaneous anaphylaxis methods were used to analyze sera. Oral exposure to native or reduced 2S albumin resulted in specific IgG1 and IgG2 responses. In conclusion, the study demonstrated that disruption of the protein structure of Brazil nut 2S albumin reduced the sensitization potential of the rat food allergy model, whereas the immunogenicity of 2S albumin was preserved. This observation can be useful for the development of immunotherapy for Brazil nut allergy. On the other hand, de Melo et al. (1994) investigated the oral administration of various doses Brazil nuts to rats as a possible route of immunization, but they found that instead of immunization, it induced systemic tolerance. Multiple feeding, than by a single dose feeding more effectively induced immune tolerance.

Brazil nut possible allergies symptoms

In general, the symptoms of anaphylactic reactions associated with Brazil nut can vary from urticaria to anaphylactic shock, and the diagnosis can be made based on medical history or using the skin prick test (SPT) to measure the presence of specific IgE. Table 5 shows some patients with symptoms from oral ingestion or contact with body fluids (semen) of an individual who had consumed Brazil nuts (Bansal et al., 2007). The proteomic approach was used to characterize the main isoforms of Brazil nut 2S albumin. Although most isoforms have molecular weight of approximately 12 kDa with a high amino acid sequence homology, significant heterogeneity was found (Moreno et al., 2014). Alcocer et al. (2012) stated that due to its extremely high content of sulfur amino acids, the allergen fraction has attracted much scientific attention as a target protein in transgenic biotechnology research, studies on processing of plant storage proteins and as an experimental protein in nutritional supplementation experiments. Some studies investigated the addition of Brazil nut protein to other foods such as soy. However, these experiments showed the allergen presence. For example, the nutritional quality of soy can be compromised by a relative
deficiency of methionine in the protein fraction of the seeds. In order to improve nutritional quality, the 2S albumin fraction from Brazil nut has been introduced into transgenic soybeans. An allergen can be transferred from one food to another through genetic engineering (Nordlee et al., 1996). Generally, immunological methods for detection of Brazil nut allergens in foods are based on polyclonal antibodies tested in animals. Phage display technology allows obtaining high affinity antibodies, avoiding animal immunization, and it can therefore apply the principle of replacement supported by animal welfare guidelines.

De La Cruz et al. (2013b) studied specific binders against Brazil nut employing a Brazil nut protein extract and a purified 2S globulin extract. A fragment (phage) that specifically recognizes Brazil nut proteins was isolated. The selected phage was also used as affinity probe to develop an indirect phage-ELISA for the detection of Brazil nut in experimental binary mixtures and processed foods. This study described for the first time the isolation of specific recombinant antibody fragments and showed the way for the development of immunoassays for the analysis of food that can be produced in vitro and do not rely on animal immunization.

Despite several previous reports on the allergenic potential of the 2S albumin protein fraction, Rundqvist et al. (2012) reported that the protein alone does not cause an allergic response in rats, but the addition of the components of a Brazil nut lipid fraction would be important. Structural details of Ber e 1 suggest that it may contribute to the understanding of the protein allergenic properties and its potential interaction partners. The overall fold of 2S albumin is similar to that of other albumsins, but the hydrophobic cavities resemble that of a homologous non-specific lipid transfer protein. The allergen proved to interact with Cu\(^{2+}\) ions. This Cu\(^{2+}\) binding has a minimal effect on the electrostatic potential on the protein surface, but the charge distribution within the hydrophobic cavity is significantly changed. Since the hydrophobic cavity is likely to be surrounded by a lipid, Cu\(^{2+}\) interaction, it can in turn affect the interaction to trigger an allergic response. On the other hand, the labeling of foods containing Brazil nut is of fundamental importance for the safety of consumers susceptible to food allergy. In order to protect sensitized individuals, reliable methods to detect trace amounts of Brazil nut should be available for the food industry and for health and food safety authorities. A TaqMan real time polymerase chain reaction (PCR) method was developed for specific detection of proteins in foodstuffs. The method uses specific Brazil nut primers, targeting the 2S albumin fraction, and a positive amplification control based on the 18S rRNA gene. The applicability of this specific system for Brazil nuts was evaluated on 66 samples of different commercial foods. The real time PCR assay proved to be a useful tool for detection of Brazil nut DNA, and it can be used as a routine analysis to assert accuracy on food labeling (De la Cruz et al., 2013a).

Other issues

Despite its beneficial nutritional properties, the mycobiota prevailing in Brazil nuts may include mycotoxins-producing fungi. Since these substances can also be associated with environmental allergies and have deleterious effects, especially on the liver, the associated risks should be considered. Brazil nut production involves several producing countries and a global supply chain. Due to the presence of aflatoxins (AFLs) produced by toxigenic fungi during storage and production of Brazil nuts, there is strong need for contamination control and monitoring (Baquião et al. 2013; Pacheco et al. 2013; Pacheco and Scussel, 2009). In samples collected in the early stages of the production chain (communities/forest), the frequency of aflatoxin positive samples was lower than that in samples that were processed or obtained from retail centers (Pacheco and Scussel, 2007). Mycotoxins have been extensively studied in terms of their mechanism of action, mutagenicity and carcinogenic activity (Andrade et al., 2012; Freitas-Silva and Venâncio, 2011). The knowledge of these mechanisms has led to the development of biomarkers such as biotransformation products and macromolecular adducts (Bando et al., 2007).

AFLs ingested through contaminated foodstuffs are absorbed in the gastrointestinal tract and are bio-transformed in the liver being activated and can therefore exert carcinogenic effects. The AFB1 activated form (AFB1 epoxide) can covalently bond to DNA, RNA and proteins. These bonds form adducts, which are primary biochemical lesions produced by AFB1 epoxide. The formation of adducts is a characteristic of liver carcinomas (Redzwan et al., 2012; Pereira and Santos, 2011). Therefore, DNA adducts reflect the variation in the aflatoxin intake daily diet, whereas albumin adducts integrate the exposure over several weeks. Quantification of exposure to AFB1 using precise and accurate laboratory methods is a relatively recent development. As an indicator of weeks or months of exposure, AFB1 Lysine (AFB1-lys) can be hydrolyzed with the patient serum. It can be quantified using isotope dilution liquid chromatography-tandem mass spectrometry (ID-LC-MS/MS) and quantified as a biomarker.

In a study conducted in the USA, for example, about 1% of the USA population had detectable levels (≥ 0.02 mg/L) of AFB1-lysine. Of those with detectable levels, the geometric mean was 0.038 (0.024 to 0.060 g/L), equivalent to 0.842 (0.530 to 1.34 pg/mg) albumin (Schleicher et al., 2013). In addition to the high protein level of some foods, such as Brazil nuts, several studies strongly indicate that there is need for guidance during post-harvesting and food handling steps and interventions in the preparation of food intended to reduce exposure to AFLs in different populations and ethnic groups (Leong et al., 2012; Jolly et al., 2006). The identification and measurement of biomarkers to assess human exposure to mycotoxins by simple, rapid,
precise and accurate analytical methods can help prevent or minimize the health harms that arise from human exposure to these substances. In conclusion, the risk assessment of Brazil nut consumption, concerning allergy, is necessary in order to provide actual information to consumers and improve the food safety and public health.

Concerning the therapeutic potential from Brazil nuts, their benefits are well known. According to Yang (2009), epidemiologic studies have shown inverse association between the intake of nuts and chronic diseases such as cardiovascular diseases and cancer. The content of lipids, minerals and phytochemicals and their health benefits associated with the consumption of Brazil nuts have been continuously reviewed. Their nutritional composition seems to have beneficial effects due to their antioxidant properties that are associated with a reduced risk of developing atherosclerosis and cancer. Still regarding their influence on human metabolism, Cominetti et al. (2012) demonstrated that obese people who consume Brazil nut daily could improve Se status and lipid profile, especially high-density lipoprotein and cholesterol levels, thereby reducing cardiovascular risks. The consumption of 3 to 5 nuts a day for 16 weeks, improved the lipid profile and microvascular function in obese adolescents, possibly due to the high content of unsaturated fatty acids and bioactive substances (Maranhão et al., 2011). In addition, it was reported a long-term decrease in inflammatory markers after a single intake of Brazil nuts in healthy individuals (Colpo et al., 2014). Nevertheless, the long-term effect of their consumption on the inflammatory markers should be further investigated.

CONCLUSION

The Brazil nut allergy is a clinical status dependable of prevention. Some strategies for consumers such as observe the ingredients content of food products and complete information for clinical treatments are necessary. More effort by the medical assistance is important to report clinic cases related to Brazil nut allergy to government agencies in order to apply the risk assessment concepts and to communicate the population about the risks of Brazil nut consumption by sensible individuals.
