ABOUT AJPP

The African Journal of Pharmacy and Pharmacology (AJPP) is published weekly (one volume per year) by Academic Journals.

African Journal of Pharmacy and Pharmacology (AJPP) is an open access journal that provides rapid publication (weekly) of articles in all areas of Pharmaceutical Science such as Pharmaceutical Microbiology, Pharmaceutical Raw Material Science, Formulations, Molecular modeling, Health sector Reforms, Drug Delivery, Pharmacokinetics and Pharmacodynamics, Pharmacognosy, Social and Administrative Pharmacy, Pharmaceutics and Pharmaceutical Microbiology, Herbal Medicines research, Pharmaceutical Raw Materials development/utilization, Novel drug delivery systems, Polymer/Cosmetic Science, Food/Drug Interaction, Herbal drugs evaluation, Physical Pharmaceutics, Medication management, Cosmetic Science, pharmaceuticals, pharmacology, pharmaceutical research etc. The Journal welcomes the submission of manuscripts that meet the general criteria of significance and scientific excellence. Papers will be published shortly after acceptance. All articles published in AJPP are peer-reviewed.

Received 4 April, 2016; Accepted 6 June, 2016

The present study is the first attempt to evaluate the hepatoprotective effect of ethanolic seeds extract (ESEt) of *Centratherum anthelminticum* (black cumin) in carbon tetrachloride (CCl4)-induced liver injury. The test doses (600 and 800 mg/kg) of same extract were found effective in their respective test groups by improving the body and liver weights, serum alanine and aspartate transaminases, γ-glutamyltranspeptidase, alkaline phosphatase, total proteins, albumin, total bilirubin, especially indirect bilirubin and uric acid levels as compared to CCl4-induced hepatotoxic control group. In addition, decreased percent inhibitions of antioxidant parameters including catalase, superoxide dismutase and reduced glutathione accompanied with increased percent inhibition of lipid peroxidation observed in both test groups. Histopathological studies also proved the liver regenerating property of ESEt by showing decrease in fatty deposition, necrosis and inflammation around the central vein of liver lobules. Therefore, the ESEt was found to be hepatoprotective and antioxidative in nature.

**Key words:** *Centratherum anthelminticum*, Carbon tetrachloride, Liver function test and antioxidants.

INTRODUCTION

Liver is the indispensable organ in maintaining the homeostasis in body by regulating metabolic and hematological functions plus bile production for fats emulsification and digestion (Hall, 2011). Besides these, diverse functions are also on its credit like storage of vitamins, iron, detoxification, removal and excretion of antibiotics, hormones, oxidative radicals and xenobiotics (Hall, 2011). However, liver's function and structure are very sensitive and can easily be affected by microorganisms (bacteria/viruses/fungi/parasites) and hepatotoxins/carcinogens (Ahmad et al., 2014). Among different liver affecting chemicals, carbon tetrachloride (CCl4), which is normally used as cleaning agent in industries, in fire extinguishers, etc., is injurious for body
Continuous inhalation of CCl₄ vapours enhanced inflammation and necrosis of hepatocytes by producing reactive metabolites that may lead to severe cirrhosis, if the condition ignored for a long time (Bigoniya et al., 2009; Singh et al., 2011). Excluding genetic causes, environmental pollutants and chemicals used in industries are also accelerating the risk of liver problems in both developed and developing countries and Pakistan is also showing highest burden of liver disorders which is chiefly contributed by mines, mills and industrial workers (Anjum et al., 2009; Malaguarnera et al., 2012; Shah et al., 2015).

In addition to the costly conventional treatments of liver problems, medicinal plants always have prominent place in this regard especially in Asian countries as these are easily available and have no toxic effects (Guan and He, 2013). Centrtherum anthelminticum (Vernonia anthelminticum Willd) belongs to the family Asteraceae and commonly known as black cumin (Amir and Chin, 2011). It is not only widely distributed in neighboring countries of Pakistan but also popular for its culinary use in all over India and Pakistan (Singh et al., 2012). Its bitter taste seeds are popular f in all over India and Pakistan but also popular for its culinary use in all over countries of Pakistan but also popular for its culinary use in all over India and Pakistan (Singh et al., 2012). However, their hepatoprotective effect has not been documented yet. Therefore, the present study is designed to investigate the effect of ethanolic seeds extract of C. anthelminticum in carbon tetrachloride (CCl₄) induced hepatotoxic rats.

MATERIALS AND METHODS

Animals

Female Wistar albino rats (180 to 220 g) were purchased from breeding house of Dow University of Health Sciences (DUHS), Karachi and kept in animal house of Department of Biochemistry, University of Karachi (UoK) according to the international guidelines of animal handling by giving them standard laboratory diet and water ad libitum.

Plant material and extraction

Seeds of C. anthelminticum were purchased and identified by authentic taxonomist (voucher no. KU/BCH/SAQ/02) of UoK. These seeds were used to prepare ethanolic extract (ESEI) according to the procedure described by Mudassir and Qureshi (2015).

Positive control and vehicle

Silimyрин (Siliver 200 mg) and dimethyl sulphoxide (DMSO; 0.05%) of Abbott Laboratories (Pakistan) Ltd and Fischer Scientific, UK, respectively were used as positive control in the present study and vehicle for administering the doses of ESEI in experimental rats.

Animal grouping and procedure

Experimental rats were divided into four groups (6 rats/group) including normal and hepatotoxic controls (group I and II), each of them treated with distilled water (1 ml/kg), positive control (group III) treated with silymarin (200 mg/kg) and test groups (groups IV and V) treated with ESEI (600 and 800 mg/kg). Each treatment was done orally once per day in early morning for 5 days consecutively. However, hepatotoxicity was induced in group II to V by intraperitoneal injection of CCl₄ (3 ml/kg in 1:1 ratio with olive oil) on 3rd and 5th day of trial after 1 h of their respective treatments. After 24 h of last dose of CCl₄, rats were sacrificed to collect blood and serum to analyze biochemical parameters. In addition, livers were dissected out carefully to weigh them, estimate antioxidant parameters and for histological examination. The present experimental procedure was approved by Board of Advance Study and Research (BASR) of UoK.

Physical, biochemical and antioxidant parameters

Percent body weight change (BWC) of rats in each group was calculated by using formula (Azmi and Qureshi, 2013) after measuring the body weights of each rat on initial (IBW) and final (FBW) days of trial. Beside this, the livers of each group were also weighed as LW (g).

\[
\text{Percent BWC} = \left( \frac{\text{FBW} - \text{IBW}}{\text{IBW}} \right) \times 100
\]

Biological parameters including alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (ALP), gamma glutamyltransferase (GGT), total bilirubin (TBR), direct bilirubin (DBR), indirect bilirubin (IBR), total protein (TP), albumin (ALB) and uric acid (UA) were measured in serum through commercially available enzymatic kits (Randox, UK). Whereas antioxidant parameters including, catalase (CAT), superoxide dismutase (SOD), reduced glutathione (GSH) and lipid per oxidation (LPO) were measured in liver homogenate by standard manual methods (Lateef and Qureshi, 2013). Percent protection in ALT, AST, and ALP of positive control and test groups against hepatotoxic control was calculated with the help of following formula (Al-Qarawi et al., 2004) where At, Ax and Ao are the mean readings of group III/IV/V, II and I of respective enzyme.

\[
\text{Percent Protection} = 1 - \left( \frac{\text{At} - \text{Ao}}{\text{Ax} - \text{Ao}} \right) \times 100
\]

Similarly, percent gain/loss in LW and TBR, IDBR, TP, ALB and UA levels in positive and test groups was calculated with formula described by Azmi and Qureshi (2012).

HISTOLOGY

Dissected out liver tissues from each group were immersed in 10% formaldeyde solution separately and sent to Dr. Essa’s diagnostic laboratory, AbulHasan Isfahani Road, Karachi Pakistan for histological studies.

Statistical analysis

One way analysis of variance (ANOVA) was used to analyze the results of present study and mentioned as mean ± SD (standard deviation). The difference of mean of each parameter was compared among all groups and found significant at p<0.05 through

\[
\text{at} - \text{ao} \quad \text{ax} - \text{ao} \quad 100
\]
RESULTS

Effect of ESEt on percent body weight change and liver weights

ESEt in doses of 600 and 800 mg/kg significantly decreased (p<0.05 and p<0.0001) the percent reduction in body weights in group IV and V, respectively as compared to hepatotoxic control group (group II) where administration of CCl₄-induced marked reduction in body weights (Figure 1). Similarly, the liver weights (g) in group II were clearly increased (p<0.0001) as compared to group III, IV and V where silymarin and test doses of ESEt were found effective in normalizing the weights of livers (Table 1).

Effect of ESEt on liver and non liver-specific parameters

Liver-specific enzymes including ALT, AST and ALP (U/l) were drastically elevated in group II whereas all same enzymes were significantly decreased (p<0.01 and p<0.0001) in groups III, IV and V which were treated with silymarin (100 mg/kg) and ESEt (600 and 800 mg/kg), respectively and showed significant percent protection especially in ALT (95 to 98%), AST (73 to 81%) and ALP (37 to 100%) (Figure 2). Whereas GGT (U/l) level was found decreased in group II (Table 1). Similarly, ESEt and silymarin were found decreasing TBR level especially indirect BR (mg/dl) in their respective groups as compared to group II (Table 1). On the other hand, TP (g/dl) and ALB (g/dl) were decreased in group II and became significantly increased (p<0.01 and p<0.0001) in group III, IV and V (Table 1). Beside these, non-liver-specific parameter uric acid (mg/dl) was found decreased prominently (p<0.0001) in the last three groups (Table 1).

Effect of ESEt on antioxidant parameters

Percent inhibitions of CAT, SOD and GSH were significantly decreased in positive control (group III) and test groups (IV and V) as compared to hepatotoxic control group II (Figure 3 and 4). Whereas, in the case of percent inhibition of LPO, an entirely opposite picture was observed in positive and test groups (Figure 4).

Effect of ESEt on histology of liver tissues

Histopathological studies were done by preparing slides of liver tissues stained with hematoxylin and eosin (Figure 5). Liver tissue (slide A) of CCl₄-induced hepatotoxic group showed degeneration of hepatocytes accompanied with fatty deposition (ballooning) and infiltration of inflammatory cells around dilated central vein in liver lobule. However, all these features of liver injury were gradually recovered in tissues (slide C and D) of groups treated with ESEt in doses of 600 and 800 mg/kg.

DISCUSSION

Liver problems, because of acquired causes, are contributing the major portion of death burden globally (Malaguarnera et al., 2012). The characteristic features of liver problems are loss of appetite and weight, elevation in liver-specific parameters and reduction in hepatic functions (Singh et al., 2011). Interesting, the same features were clearly observed in the present carbon tetrachloride (CCl₄)-induced hepatotoxic rat model. CCl₄ is a well-known liver toxicant (Adewale et al., 2014). It severely damaged cellular integrity of hepatocytes by converting itself into reactive metabolites including trichloromethyl (.CCl₃) and peroxytrichloromethyl (.OOC₃Cl) radicals after passing through hepatic cytochrome P₄₅₀ enzyme responsible for the detoxification of xenobiotic or chemicals (Khan et al., 2012).

Elevated levels of both ALT and AST are the best indicators of liver damage whereas GGT and
Figure 1. Effect of ESEt on Percent BWC. Each bar represents the mean ± SD (n=6). a and c = \( p<0.05 \) and \( p<0.0001 \) respectively when compared with group II.

Figure 2. Effect of ESEt on Liver-Specific Enzymes. Each bar represents the mean ± SD (n=6). c = \( p<0.0001 \) when compared with group II.

ALP together reflect the damage in bile duct. However, isolated elevation of AST and ALP is the warning of cardiac and bone problems as their chief concentrations are present in both these tissues, respectively (Bishop et al., 2013). In the present study, CCl\(_4\)-induced hepatotoxic control rats showed a drastic increased in ALT, AST, ALP and decreased in GGT levels. On the other hand, ALT, AST and ALP were found extensively improved in positive control and test groups treated with silymarin (100 mg/kg) and two doses of ESEt (600 and 800 mg/kg) while GGT remained low or below normal in these groups. ALT, AST and ALP are the intracellular enzymes and their abundance presence in serum above 100 to 1000 folds of their normal levels is the echo of the alteration in cell membrane intactness (Bishop et al., 2013) while decreased levels of GGT are the reflection of intrahepatic cholestasis and decreased bile acid production (Hyder et al., 2013). The alteration in cell
membrane was clearly proved by observing severe necrosis along with inflammation and steatosis (fatty deposition) in hepatocytes around central vein of lobules in microscopic examination of liver tissues of hepatotoxic group which was gradually healed up and improved by observing almost normal architecture of liver tissues that were dissected out from test groups treated with both doses of ESEt, respectively. Important point is that the ESEt of *C. anthelminticum* showed much better results as compared to silymarin in bringing the liver anatomy back to normal.

The cellular protective effect of ESEt of *C. anthelminticum* was also confirmed by observing decreased levels of uric acid (UA) in both test groups as compared to hepatotoxic control group which showed high concentration of same parameter. UA is the end product of purine metabolism and its abnormally increased concentration in serum is the alarming sign not only for the presence of kidney dysfunction but also for the degradation of body tissues or cells (Kutzing and
Figure 5. Effect of ESEt on Liver Tissue. A= CCl4-induced hepatotoxic control group that showed fatty deposition (ballooning), necrosis and inflammation around central vein. These toxic features are greatly improved in test groups treated with ESEt @ 600mg and 800mg/kg (C & D). However, inflammation and ballooning can be observed in liver slide of silymarin (100mg/kg) treated group (B).

Firestein, 2008). This beneficial effect of ESEt was more strengthened by observing a significant decrease in percent reduction in body weights of both test groups treated with same extract (600 and 800 mg/kg) as compared to hepatotoxic control which was only treated with CCl4 (3 ml/kg) and showed an extreme percent loss in body weight up to -12%. Even silymarin, the well-known hepatoprotective medicine, did not prove to be statistically efficient in this respect in positive control group.

The possible involvement of ESEt of *C. anthelminticum* in regenerating liver tissue was also fortified by estimating the normal levels of total protein (TP), albumin (ALB) and total bilirubin (TBR) both direct and indirect in extract treated test groups as compared to CCl4-induced hepatotoxic control group that showed decreased levels of TP, ALB and elevated levels of TBR particularly indirect/ unconjugated one. Literature declared that 90% of total protein, except immunoglobulin and 100% albumin are synthesized in liver (Murphey et al., 2007). However, TP and ALB can also be decreased in renal functions and malnutrition but these are considered as the best meter for evaluating the functionality of liver (Thapa and Walia, 2007). Similarly, increased serum IDBR level was not only observed in severe hemolysis but also in liver problems including hepatitis and cirrhosis with decreased or no conjugation reaction taking place in liver (Hall, 2011). Another study stated that depletion of TP induced intense mitosis in hepatocytes which leads to the enlargement of liver and this condition persists till the TP concentration becomes normal in blood (Bishop et al., 2013; Hall, 2011). Interestingly, the same happened in the present study as decreased TP and ALB was observed in hepatotoxic control group accompanied with increased liver weights, whereas improvement in TP and ALB levels in positive control and test groups also normalized the liver weights in these groups. The observed liver regenerating ability of ESEt in the present study might be by inhibiting the factors that hindered liver tissue regeneration like tumor necrosis factor alpha (TNF-α), etc (Kang et al., 2012). Amazingly, chloroform fraction of *C. anthelminticum* seeds was claimed to inhibit TNF-α in human tumor cells (Arya et al., 2012).

The antioxidant property of ESEt of *C. anthelminticum*
was already well-reported in hyperlipidemic rabbits (Lateef and Qureshi, 2013) and again became beneficial in contributing to the hepatoprotective action of same extract in the present study. In vivo induction of CCl4 stimulates severe oxidative stress by producing two trichloromethyl radicals in the presence of hepatic mixed function oxidase (Cyto P450), which reported to induce lipid peroxidation, alteration in cell membrane permeability and mitochondrial function, thereby producing reactive oxygen species (ROS) and creating tissue inflammation and necrosis (Than et al., 2015). ESET displayed radical scavenging activity in both test groups treated with same extract (600 and 800 mg/kg) by showing decrease in percent inhibition of CAT, SOD, reduced GSH and increase in percent inhibition of LPO whereas an entirely opposite picture was observed in CCl4-induced hepatotoxic group for these four parameters. The antioxidant potential of C. anthelminticum seeds might be residing in their polyphenolic content, especially flavonoids. Different extracts of C. anthelminticum seeds proved the presence of polyphenols and flavonoids having radical scavenging abilities in in-vitro assay (Ani and Naidu, 2011; Mudassir and Qureshi, 2015; Shah et al., 2007).

Conclusion

The results concluded that ethanolic seeds extract of C. anthelminticum has potent activity to reverse the harmful effects of carbon tetrachloride on liver tissues. However, further work on the same theme has to be done on its isolated compounds to know which would be the active principle in same extract having hepatoprotective activity.

Conflict of interest

The authors have not declared any conflict of interest.

Received 14 December, 2015; Accepted 28 April, 2016

Essential oils from *Croton heliotropifolius* Kunth roots and stems, popularly known in Bahia (Brazil) as velame or cassutinga, were obtained by hydro distillation. Fixed oil from the roots of this species was obtained by maceration in hexane. The oils were analyzed by nuclear magnetic resonance (NMR) and gas chromatography coupled with mass spectrometry (GCMS). 46 compounds were identified in the stems and 35 substances were found in the roots. The principal components oils were camphor, β-pinene, and α-pinene in the stems, and camphor, borneol, valencene, and viridiflorol in the roots. The fixed oil contained C8 to C18 fatty acids. It is the first study that reports the presence of fixed oil from the roots of this genus.

Key words: *Croton heliotropifolius*, Euphorbiaceae, essential oils composition, fixed oil composition, velame.

INTRODUCTION

Croton is distinguished by its morphological diversity and interintraspecific and it is the second largest genus of Euphorbiaceae, comprising around 1,200 species distributed in tropical and subtropical regions, particularly in America. Brazil is a country that congregates a large number of species, about 350 species (Lima and Pirani, 2008).

Several *Croton* species have been used in traditional medicine for different purposes (Randau et al., 2004; Vunda et al., 2012). The genus contains various substances with biological activities such as against cancer – diterpenoids (clerodane, furoclerodane and acyclic diterpenes), alkaloids (taspine), and essential oils (Salatino et al., 2007). Essential oils have also been evaluated for their larvicidal efficacy against *Aedes aegypti*, amoebicidal, antifungal, and antimicrobial activities (Salatino et al., 2007; Souza et al., 2006; Rodrigues et al., 2009; Motta et al., 2013). These oils present variable components depending on the climate and soil conditions in which the specimens are found (Maia and Ming 1998).

Amongst the species of *Croton* is found *Croton heliotropifolius* Kunth (synonymy of *Croton rhamnifolius var. heliotropifolius*), popularly known in Bahia (Brazil) as

*Corresponding author. E-mail: cinarasilva@ufba.br.

Author(s) agree that this article remain permanently open access under the terms of the Creative Commons Attribution License 4.0 International License
velame or cassutinga, is an aromatic plant, endemic species in the Northeast of Brazil, used in folk medicine as tea for gastrointestinal diseases and to alleviate fever (Randau et al., 2004). Depending on its location, C. heliotropiifolius shows great variation in size and shape of the leaves, fuzz color and length of inflorescences. It is a shrubby species that ranges from 0.7 to 2.5 m in height; it may have colorless latex or orange when oxidized. The branches are cylindrical and gray-green. Alternating leaves sub-opposite the apex of the branches and may be the entire or serrated margin. It can be distinguished from other species mainly by tripartite columella of fruit at the apex after dehiscence of the fruit (Silva et al, 2010).

Some previous studies presented variations in the composition of oils from C. heliotropiifolius stems due to the collection period and the region where the specimen was collected (Araújo-Neves and Camara, 2012; Souza et al. 2010). Araújo-Neves and Camara (2012) identified the volatile constituents of this species present in the stems collected in the region of Pernambuco, Brazil, identified guaiol (18.38%), β-elemene (17.28%) and valerianol (10.62%) as significant components of the oil. Souza et al. (2010) identified as major components of oil from stems as the α-pinene, β-pinene, camphor and germacrene D and found a significant seasonal variation in major constituents, especially the decrease in concentration in the dry season (winter).

Considering the above, this study aimed to analyze the chemical composition of volatile and fixed oils extracted from the stems and roots of C. heliotropiifolius Kunth and to check the alterations of the constituents according to region where the specimen was collected. Moreover, this is the first phytochemical investigation of constituents of fixed and volatile oils presents in the roots of Croton.

MATERIALS AND METHODS

Plant material

Roots and stems were collected in the Morro do Chapéu City located at 1011 m above sea level with highland tropical climate in the Chapada Diamantina, Bahia, Brazil. The Croton heliotropiifolius was identified and a voucher specimen is deposited in the Alexandre Leal Costa Herbarium of the Institute of Biology, at the Federal University of Bahia, Brazil under number 106168.

Oil isolation

Around 100 g of material was triturated and then subjected to hydro distillation for three hours in a modified Clevenger-type apparatus. The oil was collected from a condenser, dried over anhydrous sodium sulfate, and stored at 4°C till it was analyzed. The other portion of dried roots (784 g) of C. heliotropiifolius was macerated with 500 mL of n-hexane at room temperature. The oil was filtered and 6 mL were obtained. The fixed oil was purified by column chromatography in silica gel eluted with 20 mL of n-hexane and dichloromethane (8:2).

Chemical analysis of the oils

The oils were analyzed by gas chromatography coupled with mass spectrometry (GC-MS), the analyses were performed on a Shimadzu QP 2010 model mass spectrophotometer with ionization source of 70 eV and with a split/splitless injector, and a Shimadzu AOC-20i auto injector (Shimadzu, Kyoto, Japan). The volume of 1.0 μL of pure oil for each sample was injected at 220°C in a DBWAX column (polyethylene glycol) 30 m × 0.25 mm x 0.25 μm film thickness (Agilent J&W DB-WAX, Santa Clara, California). The analysis occurred with 1-minute sample time in the split mode, a column flow of 1.3 mL/min, a linear velocity of 41.4 cm/s, and scan between m/z 40 and 500. The oven temperature was initially set at 50°C. It was increased by 20°C/min until 240°C was reached, maintaining this temperature for 5 min. The temperature was then once again increased this time by 5°C/min until a temperature of 280°C was reached, maintaining this temperature for 30 min. Inlet pressure: 37.1 kPa. Carrier gas: He, linear velocity (u): 32.4 cm/sec. Injection mode: split (10:1).

For identification of compounds, the peaks were compared with some standards, always consulting the libraries WILEY version n°. 7 and NIST version n°s. 12 and 62.

Identification of constituents of oils

The chromatograms are shown in Figure 1 and their compositions are presented in Tables 1 to 3. The constituent’s fragmentation patterns in the mass spectra were compared with those from the libraries WILEY version n° 7 and NIST version n° 12 and 62.

RESULTS AND DISCUSSION

Essential oil composition

Sesquiterpenes were the major components in all the root and stem oils studied. These results suggest that regarding the distribution and accumulation of monoterpenes and sesquiterpenes of the root and stem oil from C. heliotropiifolius, the chemical composition of the oils is similar to that obtained by Araújo-Neves and Camara (2012) and Souza et al. (2010).

The fatty acids present in the fixed oil were oleic, stearic, palmitic, and palmitic acids. This was first observed in the family of the latter substance. Prior to this research, fixed oil was only obtained from the stems of C. cajucara Bentham. (Souza et al., 2006).

Chemotaxonomic analysis

The variability in the composition of oils shows a characteristic chemical profile of the genus Croton.

In the stems, the main components found were the monoterpenes camphor, β-pinene, and α-pinene respectively. The α-pinene is a terpene with anti-inflammatory, antifungal, and antioxidant activity and was seen in others species of Croton. β-pinene, which has antifungal efficacy, was found in a smaller number of species such as C. argyrophyloides, C. zehntneri, and C. nepetaefolius (Morais et al., 2006).

Camphor is an antiseptic found in the species *C. crassifolius* Geisel (Yang and Deng, 2009), *C. regelianus* Muell. Arg. (Torres et al., 2008), *C. cajucara* Benth (Souza et al., 2006) and *C. hieronymi* Griseb and the
borneol in *C. hieronymi* Griseb (De Heluani et al., 2005) and *C. zambesicus* (Usman et al., 2009).

In the roots, the monoterpenes camphor (antiseptic) and borneol (gastroprotective), the sesquiterpenes valencene...
(flavor and mild oxidant) and viridifloral (antiseptic, antibacterial, and anti-inflammatory) are the main constituents. Valencane was found in the leaves of C. matourensis and flowers of C. micans Swarts and viridifloral has not been found in others species of Croton (Compagnone et al., 2010). Borneol is reported principally in barks of Croton urucurana (Simionatto et al., 2007).

**Conclusion**

This paper describes for the first time the chemical composition of the fixed oil present in C. heliotropifolius's roots, as well as the volatile oils found in the roots and stems of this species with some differences from previous studies, which may be related to the region wherein the plant was collected and the stress level in the specimen used was submitted. Besides contributing to chemosystematics of the genus, this study has the perspectives to investigate the biological activities of the extracts; the phytochemical study of the polar extracts and other parts of the plant, as well as research for the future use of oil as cosmetics. It emphasizes the importance of the study of C. heliotropifolius found in the semi-arid of Bahia in order to contribute to the knowledge of the caatinga biome, unique in the world and has huge variety of plant species, but is threatened by human action. This knowledge can help promote their better preservation, creating jobs and reducing regional inequalities through sustainable exploitation of this and other plant species.
