ABOUT AJPP

The African Journal of Pharmacy and Pharmacology (AJPP) is published weekly (one volume per year) by Academic Journals.

African Journal of Pharmacy and Pharmacology (AJPP) is an open access journal that provides rapid publication (weekly) of articles in all areas of Pharmaceutical Science such as Pharmaceutical Microbiology, Pharmaceutical Raw Material Science, Formulations, Molecular modeling, Health sector Reforms, Drug Delivery, Pharmacokinetics and Pharmacodynamics, Pharmacognosy, Social and Administrative Pharmacy, Pharmaceutics and Pharmaceutical Microbiology, Herbal Medicines research, Pharmaceutical Raw Materials development/utilization, Novel drug delivery systems, Polymer/Cosmetic Science, Food/Drug Interaction, Herbal drugs evaluation, Physical Pharmaceutics, Medication management, Cosmetic Science, pharmaceuticals, pharmacology, pharmaceutical research etc. The Journal welcomes the submission of manuscripts that meet the general criteria of significance and scientific excellence. Papers will be published shortly after acceptance. All articles published in AJPP are peer-reviewed.

Received 14 February, 2017: Accepted 7 April, 2017

The purpose of this study was to understand and investigate the phytochemical and antimicrobial effects of different fractions of the methanolic extract of Corchorus capsularis leaf. For the extraction of lipophilic compounds with the help of methanol solvent system, cold extraction process was used, where the grinded coarse powder of the leaf was soaked in methanol and kept for four days for proper extraction. After that, the extract was concentrated by using rotatory evaporator and dried in room temperature. Compounds in the extract were separated according to their polarity by using vacuum liquid chromatography (VLC) and solvents of different polarity N-hexane, benzene, diethyl ether, chloroform, dichloromethane. Later, thin layer chromatography (TLC), flavonoid assay, disk diffusion, inhibitory action in nutrient broth was done for different fractions of the methanolic extract. Diethyl ether, chloroform, dichloromethane fractions showed good anti-oxidant property but poor antibacterial activity against different types of microorganism. Chloroform fraction showed good inhibitory activity against Aspergillus niger (fungus) in nutrient broth.

Key words: Corchorus capsularis, vacuum liquid chromatography (VLC), thin layer chromatography (TLC), disc diffusion method, nutrient broth, Bangladesh.

INTRODUCTION

Bangladesh is known as a growing and populated country where the majority of the community lives below the poverty level, particularly the rural areas. The general public in Bangladesh is habituated together with the local and indigenous foods. Vegetables are extremely popular in their day-to-day meals (Ullah et al., 2013). Drug
development from purely natural origins demonstrated that natural products or natural product-derived medication made up of approximately 28% of all fresh chemical entities unveiled to the market. These are typically originated from terrestrial plant life, microorganisms, marine microorganisms, etc. However, till recently, an unimportant part of the plants has been clinically examined for their therapeutic attributes (Quader et al., 1987). Jute (Corchorus capsularis L.) is a yearly bast fiber plant. It can be located primarily within Southeast Parts of Asia. Just after cotton. Plant seeds of C. capsularis L. comprised of corchorin, corchorotxin helveticoside, cardiac glycosides, corchoroside A and B, olitoriside, erysimoside, strophantidol glycosides, biosides, olioigosaccaride and olitoriside; whilst leaves comprised of saponins, flavonoids, glucoside, capsularin steroids triterpenes and several various secondary metabolites. The pharmacological experiments unveiled the fact that the plant possessed anti-inflammatory, analgesic, antipyretic, cardiac, antioxidant, antimicrobial, insecticidal and several additional pharmacological properties (Al-Snafi, 2013). Jute (white jute, C. capsularis L.; nahta jute or tossa jute; Tiliaceae family), known as a fiber plant, is a time-honored medicinal vegetable in North Africa, the Middle and Near East and Southeast Parts of Asia (Furumoto et al., 2002). The leaves from C. capsularis have been reported to hold demulcent, laxative, appetizer, stimulant and stomachic and its infusion is customarily used to cure constipation, dysentery, fevers, liver problems as well as dyspepsia. Additionally, a decoction of the roots, as well as unripe fruits, has long been used to combat dysentery. The leaves of C. capsularis are actually consumed as vegetables in numerous area of the world such as Bangladesh, Africa, Middle East and Southeast Parts of Asia, which include Malaysia, for a long period (Zakaria et al., 2007). In the present study, phytochemical and antimicrobial investigations of different fractions of the methanolic extract of C. capsularis leaf were screened. Most jute plantations are in India and Pakistan. Other producing countries are China, Taiwan and Brazil. It contains 60 to 65% cellulose, an amount lower than flax, ramie and cotton. It’s woody substance, lignin makes it less durable than other fibers. About 75% of the world's jute is used for coarse woven fabrics, sacking or burlap. It is also used in twines and carpet yarns. White jute is more commonly grown for fiber than the closely related, tussa jute (Corchorus olitorius) (Roecklein, 1958). The C. capsularis is reported to have cardiotonic, carminative, diuretic, antisynergetic, purgative, etc. (Chopra et al., 1958; Satyavathi, 1971; Rao, 1972). Natural products, particularly the ones made from higher plant life, have fascinated researchers from ancient time for their likely beneficial values. Bangladesh is actually an affluent repository of medical plants, a lot of which can be widely used in the Unani, Ayurvedic, herbal and various traditional techniques of treatments (Ramadevi, 2013; Kaisar et al., 2011). This study reported the phytochemical and antimicrobial investigations of different fractions of the methanolic extract of Corchorus capsularis leaves.

MATERIALS AND METHODS

The study of taxon of C. capsularis

Jute thrives nicely where the annual rainfall is 1500 mm, with a minimum of 250 mm in each of the months of March, April and May. Optimum necessary temperature is 18-33°C. Jute (C. capsularis) is harvested during the wet season. Farming primarily depends on pre-monsoon showers as well as moisture conditions. C. capsularis is much more water tolerant and for that reason, it can be typically grown in minimal lands, and in many cases under water logging circumstances (Islam et al., 2013).

Collection of plant and identification

C. capsularis L. was collected from Lalmohan (Ward No. 3) is an Upazila of Bholia District in the Division of Barisal, Bangladesh in the month of January, 2014 and was identified by the taxonomist of Bangladesh National Herberium, Dhaka, Bangladesh.

Methanolic extraction process

Fresh leaves were collected from the plant and dried under the sun light. Dry leaves were weighed again in electronic balance (SHIMADU ATX2204) to measure the total weight of the dry leaves. Then, the dry leaves were converted to fine powder by using a blender (Miyako, Japan). Then weight of the blended leaves measured and preserved in an air tight container. Methanol (Merck, India) was selected as the solvent for extraction from leaves of C. capsularis L. The powdered leaf (325 g) of C. capsularis L. was soaked in methanol (~ 970 ml) for 4 days and filtered by using of filter paper Filter paper (Double Rings 100 – 11 cm, HANGZHOU XINHUA PAPER Industry Co. Ltd., China). It was stirred with a clean glass rod to ensure the maximum amounts of constituents present in the blended leaves become soluble into methanol (Merck, Germany). To prevent the evaporation of the solvent and volatile compounds from the medium, the beaker was covered by aluminium foil. The extract was then concentrated with a Buchii rotary evaporator (IKA RV-10, Biotema). An aliquot of the crude methanolic extract (32.5 g) was fractionated by vacuum liquid chromatographic (VLC) technique using silica gel 10 mesh (Merck, Germany) N-hexane (Merck, Germany), benzene (Merck, Germany), diethyl ether (Merck, Germany), chloroform (Merck, Germany), dichloromethane (Merck, Germany) in increasing order of polarity. Two parts were obtained after filtration: residue and filtered part, filtered part was poured into 1000 ml round bottomed flask (Borosil, Japan) and was concentrated with the help of rotary evaporator at low temperature of 45°C and RPM of 120. When evaporation was completed, di-ethyl ether (Merck, Germany) was used for collecting the extract (Faisal et al., 2016).

Thin layer chromatography (TLC)

Different solvent fractions were analyzed by performing thin layer chromatography (TLC) to determine the composition of each
extract. TLC was done under two solvent systems. Successively, the polarity of the solvent systems was increased to get a clear graph of all the possible compounds present in the extract. The compositions of various solvent systems used for TLC: Intermediate polar solvent: Chloroform 5 ml, ethyl acetate 4 ml, formic acid 1 ml; Polar solvent: Chloroform 6.3 ml, methanol 3.5 ml, distilled water 1 ml; Spotting: It was done with capillary tube in the following sequence. Same solvent was used to prepare samples solutions for same fraction. It was then put into the TLC with the solvent. After the solvent reached the upper limit, it was seen under UV light and was exposed to 10% sulphuric acid solution, dried and then heated to 80-90°C for charring purpose. This helped in the fixation of spot and allowed it to be prominently visible. A second batch was dipped into 0.4% DPPH solution and dried while keeping in a dark place (Saha et al., 2016a).

**Anti-oxidant test**

**Total flavonoid assay**

Initially, 1.5 ml methanolic leaf solution (1 mg/ml) of three fractions (dichloromethane, chloroform and diethyl ether) was taken in test tubes and different dilution of standard solution of quercetin (2.5, 5.0, 10, 20, 30 and 40 μg/ml) were added to 10 ml volumetric flask containing 6 ml of deionized water. To the above mixture, 0.45 ml of 5% NaNO₂ was added. After 6 min, 0.45 ml of 10% AlCl₃ was added into the mixture. After 6 min, 6 ml 4% (w/v) NaOH was added and the total volume was made up to 10 ml with distilled water. Finally, 0.6 ml deionized water was added to the sample for 15 min incubation. Then, the solution was mixed well and the absorbance was measured against a freshly prepared reagent blank at 510 nm. Total flavonoid content of the extracts was expressed as mg of quercetin equivalent per g dry weight of sample (Sanadhya et al., 2013).

**Anti-microbial assay**

The antibacterial activity was carried out by the disc diffusion method using. Three different bacterial strains of Gram positive, different strains of Gram negative bacteria and fungus were used to carry out this assay. In this study, fractions obtained after VLC were tested for antimicrobial activity by disc diffusion method. Dried and sterilized filter paper discs (6 mm diameter) containing the test samples of known amounts are placed on nutrient agar medium (TECHNO PHARMCHEM, India) uniformly seeded with the test microorganisms. The antibacterial activity was carried out by using 50 μL of suspension containing ~103 CFU/mL of microorganism spread on nutrient agar medium. A disc was soaked with solutions of 50 μl of test samples and dried placed. Standard antibiotic discs (erythromycin 15 μg/disc) together with blank disks were used as a positive and negative control. Those plates are retained at the lower temperature (4°C) for 24 h to allow for highest diffusion of the test components to the neighboring media. These plates are next inverted as well as incubated at 37°C for 24 h to get the best possible growth of the microorganisms. The test components possessing antimicrobial property restrict microbial growth within the media neighboring the discs and in so doing provide a transparent, distinct area understood to be the zone of inhibition. This antimicrobial actions belonging to the test agent is then simply determined by calculating the dimension of zone of inhibition depicted in millimeter (mm). Petridishes and other glassware were sterilized by autoclaving (Hirayama, Japan) at a temperature of 121°C and a pressure of 15-lbs/sq. inch for 20 min. Micropipette tips, cotton, forceps, blank discs etc. were also sterilized. After incubation at 37°C for 24 h, the antimicrobial activity of the test agents was determined by measuring the diameter of zone of inhibition expressed in mm. After incubation, the antimicrobial activities of the test materials were determined by measuring the diameter of the zones of inhibition in millimeter with a transparent scale (Saha RK et al., 2016b).

**RESULTS AND DISCUSSION**

**Thin layer chromatography (TLC)**

The results obtained after TLC of the fractions obtained from methanolic extract of the C. capsularis leaf is shown in Figure 1 and Table 1.

**Anti-oxidant tests (total flavonoid assay)**

Determination of total flavonoids content of the fractions of methanolic extract of C. capsularis (leaves) requires a standard curve which was obtained from a series of different quercetin concentrations.

**Anti-microbial assay**

**Disc diffusion method**

After incubation of 24 h at 37°C, Petri-dishes were observed for zone of inhibition for different fractions of methanolic extract of C. capsularis leaf. The results are shown in Table 3.

**Inhibitory effect in nutrient broth**

Absorbance’s of the samples, positive control and blank before and after incubation are shown in Tables 4 and 5.

**DISCUSSION**

TLC plates were seen under UV light and different compound were found to be separated in the plates. Numbers 4 and 5 show some spots in dichloromethane, chloroform and diethyl ether. So, compounds are present in this fraction. Number 3 show spots in N-hexane and benzene after charring done in 10% sulphuric acid solution. Charring with H₂SO₄ in high temperature separated compound transformed into black color. Finally, numbers 1 and 2 show pale yellow color in dichloromethane, chloroform & diethyl ether fractions, which indicate flavonoids present in the fractions. To evaluate the antioxidant activities of VLC fraction of C. capsularis (leaves) total flavonoid assay was used. Total flavonoid content of different fractions of C. capsularis is
1. In Intermediate polar solvent. (dipped into 0.4% DPPH)
2. In Polar solvent. (dipped into 0.4% DPPH)
3. Charring done in 10% sulphuric acid solution.
4. 1 under UV.
5. 2 under UV.

Figure 1. TLC results of the fractions. Numbers 1 and 2: Showing pale yellow color in dichloromethane, chloroform and diethyl ether fractions, which indicate flavonoids are present in the fractions. Number 3– Showing spots in N-hexane and benzene after charring done in 10% sulphuric acid solution. Numbers 4 and 5- Showing spots in dichloromethane, chloroform and diethyl ether. So, compounds are present in this fraction.

different fractions of the methanolic extract of the leaf. It is shown by this research that there is not much to do in the antimicrobial section of different fractions of methanolic extract of the *C. capsularis* leaf.

**Conclusion**

The results of the preliminary studies indicated phytochemical and antimicrobial activities of *C. capsularis* leaves. Thus, the plant warrants further investigation to isolate the active constituents responsible for these activities.

**CONFLICT OF INTERESTS**

The authors declare that they have no conflict of interest.

**ACKNOWLEDGEMENT**

Received 21 February, 2017; Accepted 7 April, 2017

This study was to evaluate anti-inflammatory and analgesic effects of the aqueous extract of leaves of *Chromolaena odorata* (Asteraceae) collected in Brazzaville-Congo. Acute inflammation was induced by using the carrageenan and formaldehyde models, and chronic inflammation by the cotton pellet induced granuloma model. Analgesic effect was evaluated by using the acetic acid-induced writhing, the pressure induced by the analgesymeter as well as the pain induced by formaldehyde. The results obtained show that aqueous extract (400 and 800 mg/kg) inhibits the edema induced by the carrageenan and formaldehyde. Moreover, this extract at the doses used (400 and 800 mg/kg) significantly inhibits granuloma fabric induced by cotton pellet. In addition, aqueous extract (400 and 800 mg/kg) inhibits significantly the pain induced by the three methods used. In conclusion, aqueous extract of *C. odorata* has anti-inflammatory and analgesic effects. These observations justify the traditional use of this plant in the treatment of inflammatory pathologies and the pain.

**Key words:** *Chromolaena odorata*, anti-inflammatory, analgesic.

INTRODUCTION

In Africa, therapeutic properties of the medicinal plants had been known for several years. However, few medicinal plants were studied scientifically at the moment. In Africa, about 80% of the populations use them in the treatment of several pathologies (Etchike et al., 2011; Epa et al., 2015). In spite of the development
of synthetic drugs, the vegetable drugs in his various forms occupy a special place. Moreover, WHO recognize the traditional medicine like one of the essential elements of primary care of health: «save the plants which save the life» such is a WHO slogan which summarizes his strategy in this domain (WHO, 2014). So, to find a simple methodology of evaluation of effectiveness and security of medicinal plants is significant. Vegetable plant in these different origins contributes to the discovery of new drug used in the treatment of several inflammatory and analgesic pathologies (Abena et al., 1996). Inflammation is one reactional phenomenon operated by the body every time the integrity of its morphological and biological constants is threatened. Inflammation is not synonym of an infection, but the infection can be the cause of an inflammation (Bokia, 2016). It can present diverse symptoms such as the edema, the pain and the heat or fever. Inflammation is always accompanied by pain, so the evaluation of the pain treatment constitutes a real major stake in public health. So, searching new anti-inflammatory and analgesic drugs is necessary. Chromolaena odorata is a medicinal plant used in Congolese traditional medicine. The juice of the leaves is used to cure the wound (Bissangou and Ouamba, 1997). The previous studies undertaken in other countries give it some pharmacological properties such as: analgesic, anti-inflammatory and antipyretic (Owoyele et al., 2008), antibacterial (Etchike et al., 2011; Agban et al., 2013), anti-oxidative (Kavitha et al., 2013) and antifongic (Kra et al., 2009). This is the reason why anti-inflammatory and analgesic effects of leaves of C. odorata (Asteraceae) collected in Brazzaville-Congo in this study were investigated.

MATERIALS AND METHODS

Plant

The leaves of C. odorata were collected in Brazzaville (February, 2014). Botanical identification of the plant material was done by Dr. A. Mousamboté, botanist systematist at the Institute of Rural Development and confirmed at the herbarium where the samples of C. odorata were compared with the reference samples (number 1183/07/1965). After identification, the plant material was dried and pulverized. 250 g of powder of leaves were mixed with 2500 ml of distilled water in a heating balloon. The mixture was boiled for 15 min. After cooling and filtration, the filtrate obtained was concentrated on a double boiler (60°C). The aqueous extract obtained was kept for the experiments.

Animals

Albino rats (150 to 200 g) and albino mice (20 to 30 g) of either sex obtained from the Faculty of Science and Technology of Marien NGOUABI-University were used. They were fed with a standard feed and water ad libitum. They were acclimatized during one week before experimentation and were housed under standard conditions (12 h light and 12 h dark) and at the temperature of 27 ± 1°C. The rules of ethics published by the International Association for the Study of Pain (Zimmermann, 1983) have been considered.

Evaluation of anti-inflammatory effect of aqueous extract of C. odorata

Carrageenan induced inflammation

Method described by Elion Itou et al. (2014) was used. The animals were divided into groups of 5 rats each. Different doses of aqueous extract of C. odorata (400 and 800 mg/kg), diclofenac (standard drug, 5 mg/kg) and distilled water (control group) 0.5 ml/100 g) were administrated orally to groups, 1 h prior to the local injection of carrageenan (0.05 ml, 1%) into the plantar aponeurosis. Edema was measured by using plethysmometer (Ugo Basile, Italy) at 1/2, 1, 2, 3, 4, 5, 6 and 24th h. The anti-inflammatory effect is evaluated by the inhibition of edema (Elion Itou et al., 2014).

Formaldehyde induced paw inflammation

The rat paw edema was induced with formaldehyde 2.5% (0.2 ml/rat). The animals were divided into groups of 5 rats each. Different doses of aqueous extract of C. odorata (400 and 800 mg/kg), Tramadol (standard drug, 10 mg/kg) and distilled water (control group, 0.5 ml/100 g) were administered orally to groups, 1 h prior to the local injection of formaldehyde into the plantar aponeurosis. Edema was measured by using plethysmometer (Ugo Basile 7140, Italy) at 1, 2, 3 and 4th hour after formaldehyde administration (Mbianchta et al., 2010). The anti-inflammatory effect is evaluated by calculating the inhibition of edema.

Cotton pellet induced chronic inflammation

The effect of aqueous extract of C. odorata on granuloma formation was studied according to the method described by Elion Itou et al. (2014). 100 mg of cotton pellet were sterilized at 60°C during 24 h and placed interscapular region of rat after ether anesthesia and incision. Distilled water (control group), diclofenac (standard drug) and aqueous extract of C. odorata (400 and 800 mg/kg) were administrated orally during seven (7) days. On the eighth day, the cotton pellet was removed, cleared of from all adhering tissue and dried at 60°C for 24 h and weighed. The anti-inflammatory effect was given by the inhibition (I) of the granuloma formation (Elion Itou et al., 2014):

\[ I = \frac{(B - A)}{A} \times 100 \]

where A = weight of cotton pellet before implantation (100 mg); B = weight of dried cotton pellet after implantation.

Evaluation of analgesic effect of aqueous extract of C. odorata

Acetic acid-induced abdominal writhing in mice

The pain was induced in the mice by using 0.6% acetic acid solution (Sawadogo et al., 2011; Elion Itou et al., 2014). The animals were divided into groups of 6 mice each. Different doses of aqueous extract of C. odorata (400 and 800 mg/kg), paracetamol (standard drug, 50 mg/kg) and distilled water (control group, 0.5 ml/100 g) were administrated orally to groups, 1 h prior to the local injection of acetic acid (10 ml/kg, IP). 5 min after acetic acid injection, the number of abdominal writhing made by each mouse was recorded during 20 min. The analgesic effect was given by the inhibition (I) of the abdominal writhing (Elion Itou et al., 2014).

Analgesymeter test

The nociceptive response to pressure was measured as described...
Figure 1. Effect of the aqueous extract of Chromolaena odorata on edema induced by carrageenan in rat. Each value represents the mean ± ESM; a=p>0.05; b=*p<0.05; c=**p<0.01; d=***p<0.001 (Student t-test), versus control group. DW: Distilled water, Diclo: diclofenac, C. odorata: Chromolaena odorata.

by Mbiantcha et al. (2010) using an analgesimeter (Ugo Basile, Italy). This instrument generates a linearly increasing mechanical force or pressure on the dorsal surface on the rat's hind paw. The nociceptive threshold was the point where the animal withdraws its paw. The animals were divided into groups of 6 rats each. Different doses of aqueous extract of C. odorata (400 and 800 mg/kg), paracetamol (standard drug, 50 mg/kg) and distilled water (control group, 0.5 ml/100 g) were administered orally to groups 1 h before the measure of nociceptive threshold. After determination of the nociceptive threshold, the reaction time was calculated (Elion Itou et al., 2014).

RESULTS

Anti-inflammatory effect of aqueous extract of C. odorata

Effect on carrageenan edema

Subplantar injection of the carrageenan produced an inflammatory edema which increased gradually with a maximum between at the 4th hour after injection (Figure 1). Aqueous extract of C. odorata (400 and 800 mg/kg) induced significant (p<0.05, p<0.01 and p<0.001) anti-inflammatory effect that increased gradually and reached a maximum (56.98 and 81.75%) at the 24th hour, respectively (Figure 2). Diclofenac (5 mg/kg) shows anti-inflammatory effect (p<0.001) that was maintained all along the experiment with a maximum of (80.07%) at the 6th hour (Figures 1 and 2).

Effect on formaldehyde edema

The results are shown in Table 1. Aqueous extract of C. odorata (400 and 800 mg/kg) has no reduced the edema evolution at the 1 and 4th hour (p>0.05). However, aqueous extract (400 and 800 mg/kg) induced significant (p<0.05, p<0.01 and p<0.001) anti-inflammatory effect that increased between 2 and 3th hour after the injection of carrageenan. Tramadol (10 mg/kg) shows anti-inflammatory effect (p<0.001) and was maintained all along the experiment with a maximum of 70.03% at the

4th hour after the injection of carrageenan.

**Effect on cotton pellet granuloma**

The effect of the aqueous extract of *C. odorata* (400 and 800 mg/kg) as well as diclofenac on the granuloma is shown in Table 2. They show that the aqueous extract of *C. odorata* (400 and 800 mg/kg) as well as diclofenac induced significant (p<0.001) the formation of cotton pellet granuloma compared to the control group. Diclofenac and aqueous extract (800 mg/kg) better inhibited the formation of cotton pellet granuloma than aqueous extract (400 mg/kg) with a maximum of 49.59 and 49.84%, respectively against 19.38% for aqueous extract (400 mg/kg).

Effect on the pain induced by the analgesymeter

The effect of the aqueous extract of *C. odorata* on the pain induced by the analgesymeter is as shown in Figure 3. It shows that the aqueous extract at doses used as well as paracetamol (used as standard drug) significantly increases (p<0.001) the reaction time of the animals against the pain compared to the control group. It is also noted that the effect obtained at the dose of 800 mg/kg of the aqueous extract is more significant than that obtained with the aqueous extract at 400 mg/kg and paracetamol.

Effect on the pain induced by formaldehyde in rat

The effect on the pain induced by formaldehyde 2.5% in neurogenic and inflammatory pain responses are presented in Table 4. On neurogenic and inflammatory pain responses, the results obtained show that the aqueous extract of *C. odorata* as well as tramadol significantly reduce (p<0.001) the frequency of licking and biting the legs of the animals compared to the control group. In addition, the tramadol and aqueous extract (800 mg/kg) inhibits better the animals against neurogenic and inflammatory pain (Table 4).

DISCUSSION

Inflammation was evaluated by using the method of the acute inflammation induced by carrageenan and formaldehyde as well as the chronic inflammation induced by cotton pellet. Carrageenan is a mucopolysaccharide administrated under plantar in rats which causes an acute inflammation which is traduced by edema (Elion Itou, 2010). Edema induced by the carrageenan is biphasic. First phase (1 h) is mediated by the inflammatory mediators (serotonin and histamine) and the second phase (2 h after carrageenan administration) is mediated by prostaglandins, products of cyclooxygenase (COX) (Perianayagam et al., 2006; Sudipta et al., 2011). Aqueous extract of *C. odorata* (400 and 800 mg/kg) inhibits the evolution of edema with a maximum of inhibition of 4 h after administration of the carrageenan compared to the control group. Moreover, aqueous extract at doses used is also opposed to acute inflammation induced by formaldehyde in rat. In addition, aqueous extract of *C. odorata* (400 and 800 mg/kg) compared to the control group. The effect observed with the aqueous extract at doses used is definitely better than paracetamol used as standard drug with a difference of inhibition of 24.15% at the dose of 400 mg/kg and 27.56% at the dose of 800 mg/kg of the aqueous extract of *C. odorata*.

***p<0.001; (Student t-test). Each value represents the mean ± ESM; versus control group.

inhibits the formation of granuloma fabric compared to the reference group. These results suggest that the aqueous extract of *C. odorata* (400 and 800 mg/kg) has an anti-inflammatory effect. The inflammation can appear by various symptoms such as the edema (tumefaction or tumour), pain and heat or the fever. It is always accompanied by pain. This is why the evaluation of the analgesic effect is necessary. The analgesic effect of the aqueous extract was evaluated at the peripheral and central level. At the peripheral level, aqueous extract of *C. odorata* (400 and 800 mg/kg) showed an inhibiting effect on the pain induced by acetic acid and the analgesymeter, at the central level; it is opposed to the pain induced by formaldehyde like tramadol (standard drug). These results suggest that aqueous extract of *C. odorata* (400 and 800 mg/kg) has an analgesic effect. The phytochemical study of the extract revealed the presence of saponins, alkaloids, cardiotonic-heterosids, steroids and terpenoids as well as tannins (Bokia, 2016). The presence of the flavonoids could explain the anti-inflammatory effect (Bagli et al., 2004; O’Leary et al., 2004), flavonoids and alkaloids would explain the analgesic effect (Borgi et al., 2007; Sudo et al., 2015).

**Conclusion**

This study shows that the aqueous extract *C. odorata* has anti-inflammatory and analgesic effects. This justifies the traditional use of this plant in the treatment of the
inflammation and the pain. This study deserves to be completed in order to clarify the mechanisms of action.
