ABOUT JMPR

The Journal of Medicinal Plant Research is published weekly (one volume per year) by Academic Journals.

The Journal of Medicinal Plants Research (JMPR) is an open access journal that provides rapid publication (weekly) of articles in all areas of Medicinal Plants research, Ethnopharmacology, Fitoterapia, Phytomedicine etc. The Journal welcomes the submission of manuscripts that meet the general criteria of significance and scientific excellence. Papers will be published shortly after acceptance. All articles published in JMPR are peer reviewed. Electronic submission of manuscripts is strongly encouraged, provided that the text, tables, and figures are included in a single Microsoft Word file (preferably in Arial font).

Received 15 August, 2017; Accepted 16 October, 2017

Pentadesma butyracea is a rainforest species of Clusiaceae family with multi-values for human healthcare according to previous ethnobotanical survey. In spite of this traditional use of P. butyracea, there is a lack of scientific knowledge of its biological activities. Therefore, the aim of this study was to identify the major phytochemical compounds of P. butyracea hydroalcoholic seeds extract and to assess phyto-hormonal activities. Phyto-chemical screening of dichloromethane and hydroalcoholic seeds extracts were achieved. Subsequently, acute toxicity study was performed on mice to assess extracts safety use. Phyto-hormonal activities of hydroalcoholic extract of seeds were evaluated by uterotrophic and Hershberger’s bioassays. Phyto-chemical screening of seeds of P. butyracea showed the presence of flavonoids, tannins, phytosterols, polyphenols, leucoanthocyanes and fatty acids. Acute toxicity investigation showed no mortality of mice at the dose of 2000 mg/kg. Hydro-alcoholic extract of seeds significantly increased (p<0.05) the weight of uterus of immature female mice while prostate and seminal vesicles weight of immature male mice were significantly (p<0.05) reduced. In conclusion, the hydroalcoholic extract of seeds of P. butyracea is practically nontoxic and contains chemical groups which induced estrogenic and anti-androgenic activities. The seeds extract of P. butyracea have great potential which could be useful for management of menopausal symptoms disorders and hormone-sensitive diseases.

Key words: Pentadesma butyracea extract, phyto-chemical, acute toxicity and phyto-hormonal activities.

INTRODUCTION

Natural products including medicinal plants have a great potential for human and animal well-being. Many pharmaceutical drugs are derived from medicinal plants (Rates, 2001) and until now, people from developing countries rely mostly on medicinal plants for their primary healthcare. Furthermore, medicinal plants and diets supplement can have a great benefit for treatment or prevention of chronic diseases such as cancers and cardiovascular diseases (Liu, 2003). Therefore, with the increase of chronic diseases cases in developing countries and especially in Burkina Faso, more interest should be given to the possible contribution of medicinal
plants for healthcare of low income people. Although this natural source of medication is cheap and efficient, there is a lack of scientific knowledge with regard to safety and active dose for several medicinal plants, which limits their rational use. *Pentadesma butyracea* is one of them.

*P. butyracea* is a dense forest species belonging to Clusiaceae family. It can be found in Western African countries such as Burkina Faso, Benin, Cameroon, Ghana, Côte d'Ivoire (Sinsin et al., 2003; Ouedraogo et al., 2013; Noudogbessi et al., 2013a). It is used by traditional healers to improve lactogenic activity of mammal, to manage breast pain and to treat pregnancy disorders such as abortion (Sinsin et al., 2003; Avocevou-Ayisso et al., 2011). Previous investigations (Batista et al., 2009; Tala et al., 2013; Noudogbessi et al., 2013b) showed that *P. butyracea* has anti-tumor and anti-plasmodial activities.

Nevertheless, few scientific investigations were performed to assess its biological activities on reproduction systems. Therefore, this study was conducted for two main objectives: to identify the major chemical compounds of *P. butyracea*, and to assess its acute toxicity and phyto-hormonal effects on mice reproduction tracts.

**MATERIALS AND METHODS**

**Plant material**

Seeds of *P. butyracea* were collected in June, 2013 from Banfora town located some 440 km from the capital Ouagadougou, in western part of Burkina Faso. These seeds were identified and authenticated by the Herbarium of University Ouaga I Pr. Joseph Ki-ZERBO where a voucher specimen was deposited with a reference number (ID number: 16973, sample number: 6847). Seeds were air-dried in ventilated room, shielded from dust and sun.

**Extraction and phytochemical screening**

The dried seeds of *P. butyracea* were powdered with an electrical apparatus. One hundred gram of dried powdered was extracted in continuous extraction apparatus (soxhlet) until exhaustion successively with 500 ml of n-hexane, 500 ml of dichloromethane (DCM), 500 ml of acetate of ethyl and hydro-alcoholic solution 80% (v/v). The solvent of each extract was completely removed by evaporation (40 to 50°C) in a rotavapor. All the extracts were freeze-dried and stored at 4°C. The yield of the extraction was 39.64, 0.24, 3.8 and 12.63 % for n-hexane, DCM, acetate of ethyl and hydro-alcoholic solution, respectively. Various colorimetric tests were used on DCM and hydro-alcoholic seed extracts to identify the major groups of secondary metabolites according to Giulie (1982). The following phytochemical compounds were checked, phytosterols and triterpenes, flavonoids aglycones, anthracinsides aglycones, alkaloids, coumarins, cardenolides, fatty acids with high molecules weight, flavonoids, leuco-anthocyanins and tannins.

**Chemicals**

The 17β-estradiol (Purity 97%) was purchased from the Sigma Chemical Co. (St. Louis, MO, USA) and pantestone (testosterone undecanoate) was obtained from local pharmacy. The dimethylsulfoxid [DMSO 1% (v/v)] was used as dilution liquid for preparation of the various doses. All substances were shipped and stored in glass containers at room temperature. All solvents were of analytical grade.

**Biological studies**

**Animal model and ethic consideration**

Naval Medical and Research Institute (NMRI) mice of 5 to 7 weeks-old were obtained from the animal house of University Ouaga I Pr. Joseph Ki-ZERBO. The room temperature was maintained at 22 ± 3°C with the 12 h light/12 h dark cycle and humidity at 50 ± 10%. The animals are fed with industrial pellets with 29% protein and have free access to drinking water. All the tests were performed according to the protocols already approved by the Department of Animal Physiology of University Ouaga I Pr. Joseph Ki-ZERBO and met the international standards of animals’ study (Zimmermann, 1983).

**Acute toxicity**

Acute toxicity was assessed as described previously (Organisation for Economic Co-operation and Development (OECD), 2001) with slight modification. Seven weeks-old mice of both sex weighting 24.53 ± 5.2 g were used. Twenty-four hours before test commenced, mice were fasted 4 h before that time, drinking water was removed. Nine mice were randomly divided into 3 groups of 3 animals. One group received 1000 mg/kg body weight (BW); the 2nd: 200 mg/kg BW and the 3rd one was treated with 0.24 ml of DMSO at 1% and constitutes the control group. All the mice were observed systematically for 1, 24, 48, 72 h after administration, with intoxication syndromes and mortality recorded.

**Uterotrophic and Hershberger bioassay**

Uterotrophic assay was achieved as described previously (OECD, 2007) with slight modification. Thirty immature female mice, 5 weeks-old and weighing 15 ± 2.11 g, were randomly divided into 5 groups of 6 mice each. The first group received 0.15 ml of DMSO at 1% and was considered as blank control. The second group received 10 µg/kg of 17β-estradiol and was considered as positive control. The three other groups received 50, 100 and 200 mg/kg of *P. butyracea*, respectively. All treatments were done intraperitoneally during 3 consecutive days.

For Hershberger assay, previous guideline for OECD (2009) was used with slight modification. Thirty-five immature male mice of 6 weeks old and weighed 20 ± 2.8 g were randomly divided into 5 groups of 7 mice. The first group was treated with 0.2 ml of DMSO at 1% and considered as blank control. The second group was

Phytochemical screening of *P. butyracea* seeds showed the presence of secondary metabolites such as tannins, phytosterols, triterpenes, cardenolides and leuco-anthocyanes. Flavonoids were found only in hydro-alcoholic extract. Coumarins, alkaloids, anthracenosides and saponosides were not detected (Table 1).

### Statistical analysis

Data were presented as mean ± standard error of mean (SEM) and analyzed by using Graph Pad Prism version 5.03. One-way analysis of variance (ANOVA) followed by Dunnett’s comparison test were used to assess differences between groups. A value of p < 0.05 was considered as statistically significant.

### RESULTS

#### Phytochemical screening

Phytochemical screening of DCM and hydro-alcoholic extracts of *P. butyracea* seeds showed the presence of secondary metabolites such as tannins, phytosterols, triterpenes, cardenolides and leuco-anthocyanes. Flavonoids were found only in hydro-alcoholic extract. Coumarins, alkaloids, anthracenosides and saponosides were not detected (Table 1).

#### Acute toxicity

After 72 h, no mortality was recorded at 1000 and 2000 mg/kg. Nevertheless, sleepiness behavior was recorded.

### Uterotrophic bioassay

#### Animal body weight

Three consecutive days of treatment with hydro-alcoholic extract of *P. butyracea* seeds did not change significantly (p > 0.05) the animal body weight of groups treated with 50, 100 and 200 mg/kg BW when compared to control. Nevertheless, there were slight impairments of the body weight of animals given the extract (Figure 1).

#### Organ weight

The doses of 50, 100 and 200 mg/kg BW caused significant increase (p < 0.05) of the weight of uteri, ovaries and vagina in comparison to positive control (Figures 3 and 4). The weight of adrenal glands did not change significantly (p > 0.05) when compared to blank control (Figure 3).

### Hershberger bioassay

#### Animal body weight

After ten consecutive days of treatment, the doses 50, 100 and 200 mg/kg BW of hydroalcoholic extract of *P. butyracea* seeds did not cause significant (p>0.05) change in immature mice body weight when compared to control groups (Figure 2). Nevertheless, the body weight of these animals was slightly impaired.

#### Organs weight

The doses 50, 100 and 200 mg/kg BW did not induce...
Figure 1. Immature female mice (NMRI) body weight before and after 3 consecutive days of treatment with hydro-alcoholic extract of *P. butyracea* seeds (DMSO: dimethylsulfoxide, E2: 17-β-estradiol, Pb: *Pentadesma butyracea*).

Figure 2. Immature male mice (NMRI) body weight before and after 10 consecutive days of treatment with hydro-alcoholic extract of *P. butyracea* seeds (DMSO: dimethylsulfoxide, Pant.: Pantestone, Pb: *Pentadesma butyracea*).
significant (p>0.05) change of epididymis and testicles weight in comparison to blank control (Figure 5). In comparison to positive control, the dose of 100 mg/kg BW of *P. butyracea* induced significant reduction (p<0.05).
of testicles weight (Figure 5). Prostate weight was reduced significantly \((p<0.05)\) in comparison to control values whereas adrenals weight was significantly \((p<0.05)\) increased with the dose of 50 and 100 mg/kg BW (Figures 6 and 7). All the doses caused significant \((p<0.05)\) decrease of seminal vesicles weight in comparison to blank control (Figure 7). LABC weight was reduced significantly \((p<0.05)\) with dose of 100 mg/kg BW.
when compared to control values (Figure 5).

DISCUSSION

Phytochemical screening showed that *P. butyracea* seeds contain secondary metabolites including phytosterols, triterpenes, tannins, flavonoids and leucoanthocyanes. Previously, phytochemical investigations on bark, roots and leaves showed the presence of similar phyto-chemical compounds in this plant (Tchobo et al., 2007, 2013; Noudogbessi et al., 2013a). However, some compounds such as coumarins and saponosides found by Noudogbessi et al. (2013a) were not detected in *P. butyracea* hydroalcoholic seeds extracts. This difference could be explained either by solvent used for the extraction or by the organ or growing locality soil of plant used for the extraction (Lachman et al., 2008; Kajdzanoska et al., 2011; Noudogbessi et al., 2013a).

Several investigations suggest that phytochemical compounds have health benefits including positive impact on cancer (prostate and breast), cardiovascular diseases prevention, and menopausal symptoms management (Bacciottini et al., 2007; Lui, 2003). Among phytochemicals from plants, flavonoids are the most mentioned as phytoestrogen and therefore, well-known as the compound which could be involved in several sex hormonal activities (Koffi et al., 2009; Aguilar and Barbosa, 2014). In our two extracts, flavonoids were found only in hydro-alcoholic extract, which has been selected for toxicological and in vivo assay.

*P. butyracea* seeds and butter are used in foodstuffs and traditional medicine (Sinsin et al., 2003; Avocevou-Ayisso et al., 2011; Ouedraogo et al., 2013). For the first-time, acute toxicity of hydro-alcoholic extract of *P. butyracea* seeds on mice was investigated. No mortality was recorded and lethal dose (LD_{50}) of hydro-alcoholic seeds extract could be more than 2000 mg/kg according to OCDE 423 (2001). The extract can then be classified as practically non-toxic. Therefore its phythoendocrine activities were investigated.

Reproductive target glands function is under the control of hypothalamo-pituitary-axis through steroidal hormones regulation. Therefore, reproductive organs, especially uterus are very sensitive to estrogen which is essentially produced by ovaries of mature mammals. Ovariectomized mice or immature mice have low level of estrogen. These mice need external source of estrogen for the growing or functionality of uterus and other accessory glands. This is the principle underlying the use of uterotrophic bioassay to screen substances with estrogenic/anti-estrogenic activities (Padilla-Banks et al., 2001). Uterotrophic bioassay of hydro-alcoholic extract of *P. butyracea* seeds on immature female mice showed that the weight of estrogeno-dependent organs (uteri, vagina and ovaries) increased quite significantly. The hypothalomo-pituitary-gonadic axis of these animals was not yet functional and subsequently, the change in sex glands weight is probably due to the extract effect. These findings are consistent with Bayala et al. (2006) and Siangcham et al. (2010) who showed that estrogenic compounds induce an increase of sex glands weight, especially uterus. Indeed, estrogenic compounds cause this weight increase through mitotic activity and retention of substance in target cells, especially in uterus cell (Bayala et al., 2006; Lienou et al., 2012; Essien and...
Effiong, 2014).

Hershberger bioassay showed that the extract caused a decrease of prostate, seminal vesicles and LABC weight. The extract could mediate anti-androgenic activity. It has been reported that the anti-androgenic compounds caused reduction of androgeno-dependent glands weight (Piyachaturawat et al., 1999; Bayala et al., 2011, 2012). Anti-androgenic activity can be exhibited by two essential ways (Rashed et al., 2014). Firstly, competitive action can be mediated between androgens and anti-androgens for binding androgen receptors. Secondly, anti-androgens could inhibit 5-α reductase activity, an enzyme which controls the conversion of testosterone to dihydro-testosterone, the more potent androgen acting substance on prostate. In both instances, androgeno-dependent sex glands functionality could be reduced and lead to a weight reduction.

*P. butyracea* is useful for management of hormone-dependent diseases and menopausal symptoms. Its use as foodstuffs could have beneficial effects for prevention of hormone-dependent diseases. It has been reported that compounds which are able to interact with hormonal function can have great potential to relieve hormono-dependent related diseases (Saunier et al., 2011; Rashed et al., 2014). Many results claimed that plant extract with estrogenic activities can be used for management of menopausal symptoms (Geller and Studee, 2006; Xu et al., 2014). Furthermore, treatment with potential to decrease androgen hormone action is a good candidate for prostate disorders management (Grant and Ramasamy, 2012).

**Conclusion**

Hydroalcoholic extract of *P. butyracea* seeds is rich in secondary metabolites including phytosterols, triterpenes, flavonoids, tannins, leuco-anthocyanes. Until 2000 mg/kg of BW, hydroalcoholic extract of *P. butyracea* seeds did not cause mortality of adult mice therefore, the extract is quite safe. Biological studies revealed that the extract has estrogenic and anti-androgenic activities on immature NMRI-spell out female and male mice, respectively. Therefore, *P. butyracea* is a good candidate for management of hormono-dependent diseases such as breast cancer, prostate cancer and menopausal symptoms. Nevertheless, subsequent investigations are needed.

**CONFLICT OF INTERESTS**

The authors have not declared any conflict of interests.

*Momordica charantia* has been used traditionally for the treatment of several ailments. Some natural plant products are known to exhibit cytotoxic or anti-proliferative effects on cancer cell lines, such plants offer a promising therapeutic approach as an anti-tumor agent. In this study, the anti-proliferative effects of graded concentrations of methanol leaf extract of *M. charantia* (MEMC) at different point time was examined on vascular smooth muscle cells (VSMC), and human colorectal adenocarcinoma cell lines (HT-29) were investigated using the MTT proliferation assay. The result showed that after 24 and 48 h, the effect of MEMC on the VSMC alone and in the presence of the mitogens was more of proliferation. In the case of HT 29 cytotoxic study, the extract at all doses used caused a cytotoxic effect. The effect of the extract of *M. charantia* was more pronounced and consistent at 72 h time point exhibiting cytotoxic actions against cancer cell lines, the extract showed no toxic action to normal cells. This suggests a possible use of the plant *M. charantia* to identify compounds of possible interest in the treatment of cancer. While the extract possesses proliferative effects on the VSMCs, the reverse is the case, where it exhibited cell inhibitory effects on HT 29 cell lines indicating that the plant exhibit cytotoxic effects and could then serve as lead agents in the search for anticancer drugs from natural products.

**Key words:** Anticancer activity, *M. charantia*, HT 29, VSMC, VEGF, ET-1.

**INTRODUCTION**

Cancer refers to a series of conditions whereby abnormal cells begin to divide uncontrollably. Sometimes, cancer begins in a part of the body and then spreads to other parts, a process known as metastasis (Lewandowicz et al., 2000; Kleihues et al., 2002). Cancer is one of the major causes of death globally, it is responsible for
millions of death each year (Rachet et al., 2010); the incidence of cancer was 90.5 million with about 8.8 million deaths recorded in 2015 (Global Burden of Disease (GBD), 2015). The most common form of cancer includes lung cancer, prostate cancer, colorectal cancer, breast cancer and stomach cancer.

Cancer therapy including chemotherapy, radiation therapy, immunotherapy and stem cell transplantation is associated with various side effects (Abdel-Wahab and Levine, 2010); this implies that researches should focus on discovering novel anticancer agents that are effective with minimal side-effects. There are plant-derived formulations with potential anticancer effect (Chopra and Doiphode, 2002; Aggarwal et al., 2004); these compounds with potential anticancer activity has provided important leads for the development of clinically relevant anticancer drugs (Aggarwal et al., 2003). Antioxidant-rich foods are known to be beneficial in the prevention of cancer, cardiovascular diseases, diabetes, and other oxidative-stress-related chronic diseases (Kähkönen et al., 1999; Johnson, 2004), likewise some cancer patients use agents derived from different plants or nutrients as complementary or alternative medicines, exclusively or concurrently with chemotherapy and/or radiotherapy (Riboli and Norat, 2003).

These products if well researched can represent a new source of compounds with potential antioxidant and antiapoptotic activity. Scientific studies have identified various pharmacologically active and antioxidant compounds that have limited toxicity to normal cells (Riboli and Norat, 2003; Manach et al., 2004; Leung et al., 2009). *Momordica charantia* is a creeper belonging to the family Cucurbitaceae, with all its parts, including the fruit having a bitter taste (Basch et al., 2003; Abhishek et al., 2004). *M. charantia* contains biologically active phytochemicals including triterpenes, proteins, and steroids (Potawale et al., 2008). The triterpenes present in *M. charantia* can inhibit the enzyme guanylate cyclase which is one of the enzymes required for the growth of leukemia and other cancer cells. Physiological actions of *M. charantia* include hypoglycemia, hypolipidemia, antiviral, antibacterial, immunomodulatory and anticarcinogenic effect which is the main scope of this study (Jilka et al., 1983).

Growth inhibitory properties of *M. charantia* whole plant extract were first reported by West et al. (1971). Thereafter, many growth inhibitors have been isolated from *M. charantia* and its antiproliferative activity has been demonstrated in a variety of tumor cell lines (Akihisa et al., 2007). The fruit extract of *M. charantia* has been proven to be cytotoxic to leukemic lymphocytes thereby inducing antitumor activity in vivo (Lee-Huang et al., 1995). A number of preliminary in vitro and in vivo studies with the water-soluble extract of *M. charantia* and its various purified fractions have shown anti-cancer activity against human bladder carcinomas and breast cancers (Zhu, 1990; Anila and Vijayalakshmi, 2000).

Some proteins in bitter melon including MAP-30, MRK29, alpha-momocharin, beta-momocharin and momordin C have the ability to treat tumors and HIV (Yuan et al., 1999; El-Said and Al-Barak, 2011). Some proteins including alpha- and beta-momorcharins are known to inhibit HIV infections (Jjiratchariyakul et al., 2001).

Clinical trials have found much evidence that *M. charantia* can improve immune cell function in patients with cancer (Cunnick et al., 1990; Yuan et al., 1999). In this work, the cytotoxic activity of methanol leaf extract of *M. charantia* on cancer cell lines as well as its effects on the normal cell in vitro was examined.

**MATERIALS AND METHODS**

**Cells and reagents**

Cell Titer 96 MTT (3-(4,5-dimethylthiazol-z-y1)-2,5-di-phenyl tetrazolium bromide microculture tetrazolium technique) (Promega Corporation Cat.# G3580), Human Colorectal Adenocarcinoma Cells lines (HT-29) (Sigma-Aldrich) and Vascular Smooth Muscle Cells (VSMC) (PromoCell, Germany), agarose (Bio-Rad), dimethylsulfoxide (DMSO), Dulbecco’s modified eagle medium (DMEM) (GibThai, Thailand), foetal bovine serum (FBS 20%) (Stem Cell Technology, Canada), penicillin (100 U/mL) and streptomycin (100 μg/mL), tween-80, sodium bicarbonate, trypsin/EDTA, propidium iodide (PI), 1 mM L-glutamine, in a 5% CO₂ humidified incubator were all used.

**Collection and preparation of plant sample (Momordica charantia)**

Fresh leaves of *M. charantia* were collected from the campus of the University of Ibadan, Nigeria, in May/June 2013. The leaves were properly identified and authenticated at the Department of Botany, University of Ibadan and the Voucher Specimen (VSN: UIIH-22563) was deposited at the herbarium of the Department of Botany, University of Ibadan.

**Preparation of plant extract**

The leaves were dried at room temperature (27 ± 2°C) and pulverized to a fine powder using an electric blender. The fine powder (400 g) was soaked and extracted in 90% methanol (1 L) using Soxhlet extractor for 3 days until complete extraction. The extracts were filtered through Whatman no 1 filter paper and the filtrate was evaporated to dryness by a rotary evaporator (Yamato, Rotary Evaporator, model-RE 801, Japan) at 190 to 220 rpm and 40 to 50°C for 24 h under reduced pressure to give amorphous solid mass. The extract yield was 12%.

Cell culture

HT-29 and VSMC were procured from National Centre for Cell Sciences, Pune, India. Cells were cultured and maintained in Dulbecco’s modified eagle medium (DMEM) supplemented with 20% foetal calf serum (FCS, 20%), 1% glucose and 1% penicillin-streptomycin (Gibco® by life Technologies) in an adherent tissue culture plate at 37°C in a humidified incubator containing 5% CO₂. 96 wells microtiter plate were seeded with 5 × 10⁴ cells per well and incubated again in a humidified atmosphere with 5% CO₂ at 37°C in an incubator. When the seeded plates achieved confluency, the cells were treated with graded concentrations of methanol leaf extract of M. charantia.

Evaluation of anticancer activity

Cell viability and cell proliferation assay

The antiproliferative effects of the methanol leaf extract of M. charantia L. (Cucurbitaceae) on vascular smooth muscle cells (VSMC) and human colorectal adenocarcinoma cell lines (HT-29) were studied using the cell titre 96 MTT proliferation assay where the viable cells were seeded at a density of 5 × 10⁴ (100 µl/well). For VSMC, log concentrations of each extract at 200 and 800 µg/ml were added and incubated for 24 and 48 h time points. Incubation of the extracts in the presence of VEGF and ET-1 was also conducted at different time points. Different concentrations of the extract (200, 400 and 700 µg/ml) were added and incubated with the HT-29 cell lines for 24, 48 and 72 h time points.

MTT assay

Cell viability of HT 29 cells upon treatment with M. charantia fractions at different concentrations of 200 and 800 µg/ml, 200 µg/ml and VEGF, 800 µg/ml and VEGF, SPLC1, SPLC2 (VEGF 50 ng/ml) and SPLC3 (ET1 20 ng/ml) was assayed using MTT as described by Yedjou et al. (2006). Cells were cultured to confluence, trypsinized and plated in 96 well plates at an initial density of 10² cells/ml for cell proliferation assay. Twenty-four hours after plating, cells were treated with various concentrations (25 to 100 µg/ml) of the extract along with the control in the presence or absence of mitogens Ag II or LPS and cultured for 24 to 96 h to determine effects of treatment on cell growth. The blank sample contained medium only. MTT assay was performed at 24, 48 and 72 h. MTT assay works on the principle of the ability of the cell to reduce MTT to purple formazan in the mitochondria of living cells. The viable VSM cells were seeded at a density of 5 × 10⁴ (100 µl/well) in 96 well plates and incubated in a humidified atmosphere of 5% CO₂ and 95% air at 37°C for 24 h to form a cell monolayer. MTT assay was performed over three days. On day one, the VSM cells were trypsinized after these have confluence and on the second day the cells were treated with GK, the final volume of the media was adjusted to 100 µl and the incubation continued. On day three, 20 µl of 5 mg/ml of MTT was added to each of the 96 wells but the well used as controls have no cell. After incubation for 72 h, the cells were centrifuged at 800 rpm for 5 min and the supernatant culture medium carefully aspirated. The cells were washed twice with PBS, with of 200 µl fresh medium containing added MTT (0.5 mg/ml). Further incubation was done for three and half hours at 37°C and the medium was carefully removed. The cells were centrifuged at 800 rpm for 5 min with the supernatant aspirated, followed by addition of 100 µl DMSO to each well and then 200 µl of MTT solvent was added. This was covered with tin foil and cells agitated on orbital shakers for 15 min to solubilize formazan crystals. Thereafter, the absorbance was read using microplate reader (Tecan, Switzerland) at 590 nm. The amount of colour produced is directly proportional to the number of viable cells. This procedure was repeated for VSMC which is the normal cell and observed at 24 and 48 h point time.

Effect of M. charantia fractions on cell proliferation rate was determined by viable cell count using a hemocytometer (Lee et al., 2003). HL60 cells (10⁴ cells/ml) were placed in a 24-well plate and incubated with different fractions of M. charantia at a final concentration of 20 µg/ml for 5 days. Viable cell counts were determined on each day post-treatment using trypan blue dye exclusion assay using a light microscope (Leica, Germany).

Statistical analysis

The results were expressed as mean ± SD. Cell viability was calculated using MTT absorbance of the control and treated cells: % survival = (mean value treated sample/mean value of the untreated sample) * 100. The results were treated to a one-way analysis of variance (ANOVA) and subsequently to the Tukey multi comparison post-test using the statistical package Graph Pad prism version 5 (Graph Pad software, San Diego CA, USA). Values of α0.05 were considered as significant (Betty and Jonathan, 2003).

RESULTS

Effects of methanol leaf extract of M. charantia on VSMC

The result show that after 24 h, the effect of each extract of the plants on the VSMC alone and in the presence of the mitogens was more of differentiation and proliferation with the proliferation pronounced by the 800 µg/ml concentration at 24 h. At 48 h, the proliferation was more marked (for instance the 800 µg/ml of M. charantia in the presence of vascular endothelial growth factor (VEGF) caused 153.3% increase) except for the 200 µg/ml M. charantia in the presence of VEGF that caused 14.3% decrease in cell proliferation (Figures 1 and 2).

Effects of methanol leaf extract of M. charantia on HT 29 cell line

In this study, the extract at all doses used caused a cytotoxic effect. For instance, there was 77.1% decrease in cell proliferation for 400 µg/ml of M. charantia at 24 h. At 48 h, the cell inhibitory or cytotoxic effect was more pronounced at 200 µg/ml concentration of the extract. At 72 h point time, M. charantia at all concentrations (200, 400 and 700 µg/ml) exhibited considerable cytotoxic effects on HT 29 cell lines (Figures 3 to 5).

DISCUSSION

This study demonstrates for the first time the differentiation and regeneration ability of the M. charantia methanol leaf extract on VSMC which is the normal cell. The test concentrations did not exert a cytotoxic effect on VSMC even in the presence of mitogens. This result
**Figure 1.** Effect of methanol leaf extract of *M. charantia* on VSMC cell viability at 24 h time point. α: \( \alpha_{0.05} \) when compared with SPLC 1; β: \( \alpha_{0.05} \) when compared with SPLC 2 (VEGF 50 ng/ml); γ: \( \alpha_{0.05} \) when compared with SPLC 3 (ET1 20 ng/ml).

supports our claims in a previous study that the methanol leaf extract of _M. charantia_ caused regeneration and proliferation of pancreatic beta cells.

In the case of HT 29 cytotoxic study, the extracts at all doses used caused a cytotoxic effect. There was 77.1% decrease in cell proliferation for 400 µg/ml of _M. charantia_ at 24 h. The effect of the extract of _M. charantia_ was more pronounced and consistent at 72 h time point. Chia-Jung et al. (2012) reported that _M. charantia_ extract causes mitochondria-related cell death in human cancer cells through Caspase- and mitochondria-dependent pathways. Thus methanol leaf extract of _M. charantia_ exhibited cytotoxicity on HT 29 cells, due to its ability to induce cell death in cancer.

The result from this study showed that while the extract had proliferative effects on the VSMCs, the reverse is the case, where it exhibited cell inhibitory effects on HT 29 cell lines indicating its cytotoxic effects. This study is consistent with the reports of Jutamas et al. (2015) which explained that plumerin isolated from _M. charantia_ vine exerts antiproliferative effects against leukemic, breast and liver cancer cell lines.

Terpenes, a phytochemical present in _M. charantia_ (Chang et al., 2008) have been reported to have anti-proliferative effect (Akhisa et al., 2007). This suggests that terpenes contributed to the anti-proliferative effect of _M. charantia_ observed on the cancer cell lines.

The findings of this study negate the report of Soundararajan et al. (2012) which explained that _M. charantia_ seed fractions did not exhibit any antiproliferative activity. However, Soundararajan et al. (2012) reported that the differentiation-inducing fraction in _M. charantia_ was non-proteinaceous in nature, showing that the differentiation-inducing factor of _M. charantia_ is different from its antitumor factors. Thus, the present study for the first time describes the differentiation inducing action of the methanol leaf extract of _M. charantia_ which can be further studied as an inducer of differentiation and regeneration of normal cell, either alone or combined with the suboptimal concentrations of other known inducers of differentiation.

As a result of this study, it can be recommended that the methanol leaf extract of _M. charantia_ can be combined with the known anticancer agent in order to act synergistically for a more effective treatment of cancer. The rationale being that the commercially available anticancer drugs in high concentrations not only kill cancer cells but also healthy normal cells in the body (Nagasawa et al., 2002). Therefore, a low to moderate dose of the anticancer drug (either temozolomide or vinblastine) can
be combined with a high dose of the crude methanol extract of *M. charantia* to produce a maximal anti-cancer effect, without killing healthy cells.

**Conclusion**

This study has demonstrated that the crude methanol leaf extract of *M. charantia* can cause a significant decrease in cancer cell viability (an increase in cell death) without being harmful or injurious to healthy cell lines like smooth muscle cell line. These effects were both time and dose-dependent with maximal effect occurring after 72 h at a dose of 200 μg for the methanol leaf extract of *M. charantia*. Therefore, *M. charantia* is cytotoxic to cancer cell lines (that is, it has anticancer property since it induces cell death) while it has no cytotoxic but caused regeneration of normal cells. Thus, *M. charantia* represents a promising candidate that could be developed for cancer prevention and treatment in the future.
