Received 29 November, 2014; Accepted 9 February, 2015

Magnetic field is considered a simple and cheap method for stimulation of germination process compared to traditional chemical processes. In this research, laboratory experiment was conducted at Seed Technology Unit, Mansoura, Egypt to evaluate the effect of magnetic field on germination, seedling growth and cytogenetic characters of fresh and carry over (old) onion seeds (c.v.Giza Red). Seeds were magnetically pretreated by different magnetic field (0.03 or 0.06 T) using static magnetic device for different periods time (30, 60 and 90 min). The obtained results indicated that magnetic field treatment increased all germination and seedling growth characters compared with control. Exposed fresh and carry over seeds to 0.06 T with 30 min gave the heights values of germination percentage, germination rate, speed germination index and seedling growth parameters, that is, seedling length, seedling dry weight, seedling vigor I and seedling vigor II. Whereas, mean germination time was decreased using 0.03 T with 60 min gave maximum values in carry over seeds and with 60 min in new seeds. Also, the results showed significant increase in mitotic activity and chromosomal aberration after 30 min treatments for both doses of fresh seeds and with 0.06 T of carry over seeds, while relative division rate (RDR) gave positive values and little disturbance in mitotic phase index. However, the percentage of mitotic abnormalities increased after all exposure treatments. It could be concluded that utilization of magnetic field could enhancement of germination of onion seeds but we need to be carry out more experiments to make magnetic map for all varieties of onion.

Key words: Magnetic field, germination, mitotic activity, phase index, relative division rate, mitotic aberrations.

INTRODUCTION

Onions are an important food crop worldwide. Since many years one has been observing problems with storing onion seeds. Seeds generally have a relatively short storage life and viability decreases rapidly. The main reasons of low quality of onion seed listed: Long flowering period resulted in different stages of seed maturity in the umbel and suboptimal storage conditions as high temperature and relative humidity (Brocklehurst, et al., 1985).

For this reason, for many years there have been
research works to improve seed germination and to prolong their use for sowing (Kelly, 1998). The improvement in seed germination have been achieved by different pre-sowing treatments including various physical factors such as electric field, magnetic field, laser radiation and microwave radiation (Pietruszewski and Kania, 2010). Over the years, the effects of magnetic fields on plant life have been the subject of different research studies. The first studies were conducted by Savostin (1930) who reported 100% increase in the rate of elongation of seedlings under the influence of magnetic condition. Recently, many authors have reported that magnetic field was affective on seed germination, seedling growth, reproduction and growth of meristem cells and chlorophyll quantities (Namba et al., 1995; Atak et al., 1997; Reina et al., 2001; Amera and Hozayn, 2010a, b; Hozayn et al., 2014). Magnetic field had a positive effect on photochemical activity, respiration ratio and enzyme activity (Martinez et al., 2000; Phirke et al., 1996; Carbonell et al., 2002). The reason of this effect can be searched in the presence of paramagnetic properties in chloroplast which can cause an acceleration of seeds metabolism by magnetic treatment (Aladjadjiyan and Ylieva, 2003). Physiological mechanisms of magnetic field on germination and seedling growth are not completely understood. Magnetic field treatment of seeds leads to acceleration of plants growth, proteins biosynthesis and root development (Kordas, 2002). Racuciu et al. (2008) reported that the activities of some enzymes were increased by exposure to magnetic field. Copeland and Donald (1995) reported that the effectiveness of the magnetic field stimulation is evaluated based on two parameters. These are: Energy of germination and capacity of germination. A result of higher energy of germination is often, stronger development of a radicle, increased fresh mass of the whole seedling and thereafter a plant. This, usually, results in better plant useful characters, e.g. yield of roots, bulbs or leaves (Kubisz et al., 2012) found that exposure onion seeds to magnetic field (20 mT) for 60 min increased their germination % from 4.6 control to 22%.

Recently some magnetic devices have been developed by Magnetic technologies L.L.C., Box 27559, Dubai, UAE with the claim that after passing through these devices get bio-stimulated. This magnetized seed exhibits better results in terms of germination and plant growth. Keeping in view their claim, the current study was undertaken to determine the influence of magnetic treatment on germination, seedling growth rate and cytogenetic in onion.

MATERIALS AND METHODS

This study was conducted at Seed Technology Unit, Mansoura, Egypt to evaluate the effect of magnetic field on germination characters of fresh and carry over (old) onion seeds. Onion seeds (c.v.Giza Red) production of season 2012 (carry over seed) and 2013 (fresh seed) were obtained from Onion Research Department, Field Crops Institute, Agriculture Research Centre, Giza, Egypt. Seeds immersed in 5% NaOCl (Sodium hypochloride solution) for 5 min to avoid fungal invasion. Seeds were exposed to magnetic field through rimming it in static magnetic device (Magnetic Technologies L.L.G) (Figure 1) with 0.03 or 0.06 T for different periods time (30, 60 and 90 min). Germination tests were performed according to ISTA (1999), while 300 seed of onion were sown in 3 replicates in 20±1°C in sterilized Petri dishes covered at the bottom with two sheets of Whitman filter paper that had been autoclaved and germination was performed daily to study the following characters:

1. Germination percentage defined as the total number of normal seedlings at the end of the test after twelve days.
2. Germination rate (GR): It was defined according to the following formula of Bartlet (1937):
   \[ GR = \frac{\text{No. of germinated seed}}{\text{Days of final count}} \times 100 \]
   Where a, b, c are No. of seedlings in the first, second and third count, m is No. of seedlings in final count, n is the number of counts.
3. Speed germination index (SGI): It was calculated as described in the Association of Official Seed Analysis (AOSA, 1983) by following formula:
   \[ SGI = \frac{\text{No. of germinated seed}}{\text{Days of first count}} \times 100 \]
4. Mean germination time (MGT): It was calculated based on the equation of Ellis and Roberts (1981):
   \[ MGT = \frac{\sum D n}{\Sigma n} \]
   Where (n) is the number of seeds, which were newly germinated on day, D is number of days counted from the beginning of germination.
5. Seedlings length (cm): It was measured of ten normal seedling after 12 days after planting.
6. Seedlings dry weight (gm): Ten normal seedlings 12 days after planting, the seedlings were dried in hot-air oven at 85°C for 12 h to obtain the seedlings dry weight (g).
7. Seedling vigor was calculated following Abdul Baki and Anderson (1973) as:
   \[ \text{Vigor index I} = \text{Germination} \times \text{Seedling length} (\text{Root + Shoot}) \]
   \[ \text{Vigor index II} = \text{Germination} \times \text{Seedling dry weight} (\text{Root + Shoot}) \]

Cytogenetic analysis

After both fresh and carry over germinating roots were grown until they reached about 1 to 1.5 cm in length. The root tips were then used for cytogenetic investigation and analysis. Roots were fixed in ethanol : acetic acid (3:1) for 24 h, hydrolysed in 1 M HCl for 10 min then stained with aceto-orecin for 24 h. Root tips were cut off in a drop of 45% acetic acid, macerated and squashed (Sharma and Sharma, 1980). Three replicates were performed for each mentioned treatments and scoring about 2000 cells was done from at least 5 roots of each replicate. Mitotic Index (MI), frequencies of mitotic phases (prophase, metaphase, anaphase and telophase), relative division rate (Relative division rate (RDR) ) calculated by the formula (Hoda et al., 1991):

\[ \text{RDR\%} = \frac{\% \text{ of dividing cells in treated sample} - \% \text{ of dividing cells in control sample}}{100} \times 100 \]

\[ \text{RDR\%} = \frac{\% \text{ of dividing cells in control bulbs}}{100} \times 100 \]
Mitotic abnormalities were used as endpoints for determination of cytogenetic effects. The MI was calculated as the ratio between the number of mitotic cells and the total number of scored cells and expressed as percentage. The frequency of mitotic abnormalities was expressed as a percentage in relation to the number of cells in mitosis. The most frequent abnormalities are shown in photomicrographs.

Statistical analysis
Data were statically analyzed using an analysis of variance (ANOVA) of completely randomized design (MSTAT-C v. 3.1., 1988). Least Significant Difference (LSD) was applied to compare mean values.

RESULTS

Germination traits
General results showed that magnetic field enhanced seed germination and seedling growth parameters comparing with untreated seeds.

Data presented in Table 1 showed that significant effect on Germination % (G), Germination Rate (GR) and Speed Germination Index (SGI) and Mean Germination Time (GMT) occurred by exposes carry over and new onion seeds for two magnetic field (0.03T and 0.06 T) at different time exposure (30, 60 and 90 min) compared to untreated seeds. Regarding germination percentage, the highest values achieved by exposing seeds to 0.06T for 30 mint in new and carry over onion seeds where G (%) increased from 82 and 54% in control to 90 and 70% on new and carry over seed, respectively. Germination rate increased from 0.729 in control to 0.793 when exposed to 0.03 T at 30 or 60 min on new seeds and from 0.688 to 0.739 when exposed to 0.03 T at 30 min on carry over seed. SGI increased from 23.48 to 35.72 in new seed and from 18.44 to 22.96 in old seed. Whereas, using 0.03 T with 30 min gave the maximum increase in G%, GR and SGI on new seeds and with 60 min on old seeds. Data in the same table show that significant decrease in mean germination time in magnetically treated onion seeds. Whereas the minimum MGT 2.87 and 3.45 were occurred from treated seed with 0.06 T for 30 min in new and carry over seeds. MGT decreased (3.35 to 3.43) in 0.03T with 30 min in new seed and (3.32 to 3.80) with 60 min in carry over seed.

It could be concluded that, using 0.03T with 30 min gave the maximum increase regarding new seeds and with 60 min on carry over seeds in above mentioned characters compared to untreated treatment.

Seedling growth
Regarding to seedling growth characters, results clear that a positive effect of different magnetic treatments on seedling length and dry weight, seedling vigor and seedling vigor index compared with untreated treatment (Table 2). The maximum increases were resulted from using 0.06T for 30 min in new and carry over seeds in all mentioned parameters. These increases reached to 58.50, 46.66, 49.13 and 74.15% in new seed and to 109.52, 72.72, 78.54 and 115.90% in carry over seed at the above parameters, respectively compared with control treatment. On the other hand, exposing seeds to 0.03 T gave the highest values with 30 min on new seeds and with 60 min on carry over seeds.

Cytogenetic analysis
Mitotic index (MI) results showed significant increase after all magnetic treatments for both fresh and carry over seeds as shown in Table 3. For fresh seeds, exposed for 30 min gave the highest values in both doses 0.03T and

0.06T which recorded values (13.30 and 14.13), respectively compared to control (10.42), while exposing carry over seed for 30 and 60 min gave the highest values at 0.03T (11.15) and 0.06T (10.68). Relative division rate (Relative division rate (RDR) ) gave positive values after all magnetic treatments for both seeds coordinate with the increase in mitotic index and germination (Table 3). In the same table, phase index showed little disturbance decreasing or increasing in their values. Where in fresh seeds (0.03 T for 60 min) treatment found to have the pronounced change in prophase which decreased about 9.52% compared to control as well as in carry over seeds (0.06 T for 90 min) treatment was increased about 25.71% compared to control.

Relative division rate (RDR) had positive values after all magnetic treatments (Table 4), where the maximum increase was recorded in fresh seed which exposed to 0.06 T for 30 min. Data in the same table show significant increases in Aberrations index (AI) (chromosomal aberrations) under magnetic treatments compared to control. Where, exposing fresh seeds to 0.06T for 90 min treatment had the highest aberration with (3.05) compared to control (0.27) as well as for carry over seeds at 0.06 T with 90 min treatment (2.50) value compared to control (1.20). Generally, the recorded aberration percentage in this study found to be not lethal. Stickiness and micronucleus were the most recorded chromosomal aberration types; more pronounced were observed when both fresh and carry over seeds exposed to 0.06 T for 90 min, laggard chromosome and binucleolate cell also recorded (Table 4 and Plate 1). Magnetic field treatments improved germination parameters of fresh and carry over onion seeds (Table 1).
Table 3. Effect of magnetic field treatments on mitotic index (MI), aberration index (AI), relative division rate (RDR) and phase index (P=Prophase, M=Metaphase, A=Anaphase and T=Telophase) of fresh and carry over onion seeds.

Studies made on various plants have shown that positive effects of magnetic field on seed germination. Kubisz et al. (2012) showed that low frequency of magnetic field (20 mT) can be successfully used to improve germination of onion (4.6 to 22%). Also, they recorded that treated onion seeds (cultivar Eureka) with 20 mT for 60 min increased their energy of germination from 40 to 63%, which improves evenness of plants emergences in the
Plate 1. Types of chromosomal aberrations resulted from the treatment of *Allium cepa* seeds (fresh and carry over) with magnetic field, (a-b) stickiness, (c-d) micronucleus, (e) binucleolate nucleus, (f-g) bridge and (h) laggard chromosome.

field and has a significant importance for horticultural practice. Celestino et al. (2000) observed that germination was faster for seeds exposed to the magnetic field than those in the control group, and germination percentage increased. Alexander and Doijode (1995) reported that pre-germination treatment improved the germination and seedling vigor of low viability onion and rice seeds. In treated wheat seeds germination was raised from 45.3 to 49.3% (Ijaz et al., 2012). Flórez et al. (2007) observed an increase for initial growth stages and an early sprouting of rice and maize seeds exposed to 125 and 250 mT stationary magnetic fields. Magnetic field treatment of seeds leads to acceleration of plants growth, proteins biosynthesis and root development (Kordas, 2002). Carbonell et al. (2002, 2004) found that magnetic treatment produced a biostimulation of the germination. The activities of some enzymes were increased by exposure to magnetic field (Racuci et al., 2008). Stress enzyme like APX and SOD increased in seedling which was grown from pretreated seeds, these stress enzymes have antioxidant mechanism they scavenge free radicals and decrease oxidative stress (Azita and Ahmad, 2009). Ahmad et al. (2010) showed that Mean germination time (MGT) significantly increased when the time of seed exposed at magnetic field treatments increased, about 3 and 2 h respectively for Omid and BCR wheat cultivars.

Regarding to seedling growth, our results clear that a positive effect on testing parameters seedling length, seedling dry weight, seedling vigor and seedling vigor index (Table 2). Similar results were obtained by Kubisz et al. (2012), they observed that clear differences in the length of radicals and fresh mass of seedling, longer radicals and bigger seedling than the ones from the control on the onion seeds exposed to magnetic field. Waleed et al. (2013) showed that root length, length of radical, dry weight of root and radical increased by 18, 12, 0.52 and 43%, respectively when exposed wheat seeds to (50 mT/30 min). Azita and Majd (2009) showed that the Lentil seedlings from seeds magnetically pretreated grew taller and heavier than untreated controls, they showed greatly improved root characteristics. Magnetic field treatment of seeds led to acceleration of plants’ growth, protein biosynthesis and root development (Hirota et al., 1999; Pe-uelas et al., 2004; Amera and Hozayn, 2010a, b; Hozayn et al., 2014). Aladjaadijian (2005) concluded that magnetic field increased the shoot and root regeneration rate and their fresh weight in soybean and paulownia organ cultures. Azita and Ahmad (2009) suggested that pretreated plants by magnetic fields are more resistant against harmful environmental factors. Regarding cytogenetic parameters, magnetic treatment at low frequencies exerts significant increase the mitotic index in meristematic cells of *Allium cepa* and induces chromosomal aberration (Tables 3 and 4 and Plate 1). Similar results were recorded by Tkalec et al. (2009); they showed a significant increase of mitotic index in *A. cepa* roots after 900 MHz electromagnetic field exposure as well as mitotic abnormalities increased. Aksoy et al. (2010) found that mitotic index of *A. cepa* was significantly increased at 0, 10 and 25 m distance from magnetic field treatments compared with control, MI analysis showed significantly increased the cell division a dose dependent manner in *A. cepa* L. and in *Triticum baeoticum* Boiss. As well as they found differences in mitotic phases in both
plants. Marcano et al. (2004) considered mitotic index a parameter that allows one to estimate the frequency of cellular division. Root growth depends on mitotic activity and cell elongation (Evseeva et al., 2005); these processes could be influenced by magnetic field. Moreover, Marcano et al. (2004) considered mitotic index a parameter that allows one to estimate the frequency of cellular division. Root growth depends on mitotic activity and cell elongation (Evseeva et al., 2005); these processes could be influenced by magnetic field.

Aberration percentage in this study is found to be not lethal. The chromosomal aberrations resulting from magnetic exposure might be due to the direct interaction with moving electrons within DNA (Blank and Goodman, 1998). Eren et al. (2010) found various types of mitotic defects in MF-exposed lentil roots, such as stickiness, c-mitosis, micronuclei, double nuclei. Induction of chromosomal aberrations, such as stickiness, has long been known to occur in response to many environmental agents, including chemical mutagens (Yumurtacı et al., 2007; Türkoğlu, 2009) and certain kinds of magnetic or electric fields (Rapley et al., 1988). Chromosomal aberrations (CA) occur due to lesions in both DNA and chromosomal spindle protein causing genetic damage (Amin, 2002), and may be induced by other factors, such as DNA breaks, inhibition of DNA synthesis and replication of altered DNA. Cell metabolism is sensitive to a range of nonspecific weak treatments that do not directly affect receptors or any other specialized cell structures (Racuci, 2011). While Tkalec et al. (2009) found exposure of A. cepa to magnetic field under most of the test conditions induced a significant increase of mitotic activity in root tips of A. cepa compared with control. This study may proof that MFs altered rates of DNA, RNA, and protein synthesis as other previous studies (Goodman et al., 1993; Greene et al., 1993; Zhao et al., 1999). Magnetic fields affect the synthesis of DNA and RNA as well as the cellular proliferation. EMFs in both extremely low frequencies activate the cellular stress response, a protective mechanism that induces the expression of stress response genes (Ruediger, 2009). Consequently, MFs alters gene expression, protein biosynthesis, enzyme activity, cell reproduction and cellular metabolism (Nirmala and Rao, 1996). Studies on the meristematic cells of plants have shown that magnetic field effects normal metabolisms and has impact on cellular division (Belyavskaya et al., 1992; Dhawi et al., 2009).

Different studies evident that MFs of different intensities causes certain genotoxic effects in plants. During mitosis and meiosis both these fields are supposed to cause a number of chromosomal aberrations including stickiness, lagging chromosomes, micronuclei formation, bridges, multipolar division etc. (Racuci et al., 2009; Aksoy et al., 2010; Zaidi et al., 2012; Zaidi et al., 2012). Induction of different types of chromosomal aberrations (Garcia-Secrado and Monteagudo, 1991; Nordenson et al., 1994). Stickiness may be due to degradation or polymerization of chromosomal DNA (Darlington and Mc-Leich, 1951) or may be due to defective functioning of one or two types of specific nonhistone proteins involving chromosome organization (Turkoglu, 2007). Some chromosomal aberrations induced by suitable MF exposure time of plant seeds may persist in the next generations so that some phenotypic characters may be modified (Racuci, 2011) and these modifications could be observed following the plant development, some of them being benefit for the cultivation of this species (Attia et al., 2014). This way, the extremely low frequency MF could represent the molecular basis of a putative tool in the biotechnology of plant growth, an important species in the human life, with the advantages of being less toxic and most easy to manipulate in comparison to ionizing radiation for instance (Racuci, 2011). Chromosomal aberrations that could cause delayed prophase and/or metaphase leading to an increased mitotic index (Evseeva et al., 2005).

Conclusion

The obtained results indicated that magnetic field exposure increased all germination characters compared with control. Exposed carry over and fresh onion seeds to 0.06 T with 30 mint gave the greatest values of germination percentage, germination rate, germination energy, speed germination index and seedling vigor (seedling length (cm), seedling dry weight (g). seedling vigor I and seedling vigor II). Whereas, Mean germination time was decreased. Using 0.03T with 60 mint gave maximum values in carry over seeds and with 60 min in new seeds. Significant increase in mitotic activity and chromosomal aberration after treatment with both doses for 30 min in fresh seeds and with 0.06 T in carry over seeds, while Relative division rate (RDR) gave positive values and little disturbance in mitotic phase index. However, the percentage of mitotic abnormalities increased after all exposure treatments. Hence, change in protein biosynthesis. The previous results indicate the change in cellular proliferation at low magnetic frequencies.

Conflict of Interest

The authors have not declared any conflict of interest.

ACKNOWLEDGEMENT

This work was funded by The National Research Centre through the project entitled “Utilization of magnetic technology in Egyptian Agriculture. The principal investigator is Prof. Dr. Mahmoud Hozayn.
