Accepted 19 May, 2011

Gulf of Edremit is an important center of trade, coupled with its sandy beaches, shores and towns that are surrounded by green olive trees (Ayvalık, Edremit, Burhaniye and Havran). It is also one of the largest districts of Balıkesir Province. Macrofungi are ideal food for people because they have a fairly high content of protein which contains all of the essential amino acids. They are also a source of dietary fibre, and are virtually free of cholesterol. The edible native fungi are cultivated and exported to the markets by many countries. This study was done based on the edible macrofungi specimens collected from Edremit Gulf (Edremit, Havran, Burhaniye) between 2007 and 2009. The collected fungi samples were photographed and their morphological and ecological properties and information gathered from the rural people were noted in the field notebook. Fungi were investigated morphologically in the laboratory, and then samples were dried in the oven to preserve them as herbarium samples. 10 edible fungi species belonging to nine families were identified. Six of them are consumed by local people and sold in local markets.

Key words: Edible macrofungi, Edremit Bay, Balıkesir, Turkey.

INTRODUCTION

Fungi are ideal food because they have a fairly high content of protein (typically 20-30% dry matter as crude protein) which contains all of the essential amino acids. Fungal biomass is also a source of dietary fibre, and is virtually free of cholesterol. Mushrooms are cultivated around the world, global annual production being in the region of 8 million metric tonnes (Moore and Chiu, 2001). Macrofungi studies have long been of interest to scientists as well as the public due to their important roles in human life, such as their beneficial and harmful effects on forests, their use in the pharmacology industry, and the mass production of cultivated fungi in the food industry, as well as their vital role in biodegradation (Stojchev et al., 1998). Macrofungi have a potential of being used as both nutritive and medicinal food stuff. Macrofungi are not only sources of nutrients but also could be used to prevent diseases such as hypertension, hypercholesterolemia and cancer (Altuner and Akata, 2010).

Climate and vegetation in Turkey, especially in the Western, Northern and Southern regions are suitable for wild mushrooms to grow. The vegetations of the regions show a great variation and complexity. They range from coniferous to broad leaves tree forests. The Black sea region is rainy throughout the year. Aegean and Mediterranean regions have a mild and rainy climate in coastal parts and cooler in the inner parts of the regions. The dominant vegetation of Balıkesir Province reflects typical characteristics of Mediterranean plant community and climate. In addition, Pinus sp. and Quercus sp. trees are very common in the region. Since climatic and vegetational characteristics of the region are suitable, it has a rich macromycota population (Yılmaz Ersel and Solak, 2005).

The research area covered Edremit, Havran and Burhaniye (Balıkesir) districts (Figure 1). The local geography is within the Mediterranean phytogeographic region, although it contains elements of the Europe-Siberia and Iran-Turan phytogeographic regions (Sütğibi, 2003). Many studies have been carried out on the macromycota of Turkey between 1932 and 2010. About 1936 macrofungi taxa have thus far been reported from Turkey (Servi et al., 2010). From a review of the relevant literature, it appears that no previous studies of the macromycota have been carried out in Edremit Bay.
However, some research has been carried out around Balıkesir (Aşkun and İşlioğlu, 1997; Yılmaz and İşlioğlu, 1997).

This paper presents an overview of the more common edible macrofungi eaten by the Turkish people, of the Southern-East of Turkey. The aims of this study were to determine the macrofungi taxa of Edremit Bay, to identify edible, inedible and poisonous species and to make a contribution to the macrofungal flora of Turkey.

MATERIALS AND METHODS

Macrofungi specimens were collected from different localities in Havran, Burhaniye and Edremit between 2007 and 2009, particularly during autumn and spring. The morphological and ecological characteristics of the specimens were recorded and photographed in their natural habitats, and then, brought to the laboratory. The local consumption of macrofungi and their local names were recorded by interviewing local people.

Specimens, dried in place without direct sunlight, were numbered and placed in sealed bags. In addition, they were put into a deep freezer for a week against internal and external parasite attacks (Yılmaz Ersel and Solak, 2005). The identification of taxa was carried out according to literature (Philips, 1981; Moser, 1983; Buczacki, 1989; İşlioğlu and Watling, 1992; İşlioğlu et al., 2008). Fungus’ names, authors, locality numbers, habitats, collecting dates, collector’s names and numbers were given in floristic list, respectively. All specimens collected were kept in the Herbarium of Balıkesir University, Department of Biology. The collection localities in the study area are shown in Figure 1.

RESULTS

10 edible macrofungi taxa belonging to nine families were identified. The species and local names are given in Table 1. For each taxa, habitat, locality, collection date, altitude and herbarium registration numbers were given also.

Edible macrofungi of Edremit Gulf

Ascomycetes

Discinaceae Benedix

1. Gyromitra elata Fr.
Balıkesir, Havran, Tepeoba village; 39° 37.938 N - 027° 06.168 E, 346 m April 2009 (RP 24, RP 25).

Morchellaceae Rchb.

2. Morchella elata Fr.
Balıkesir, Havran, Çakırdere village, Dişka taşi district; 39° 28.719 N - 027° 08.995 E, 470 m, April 2009 (RP 3, RP 4).
Balıkesir, Burhaniye, Sübeylidere village, 39° 24.418 N - 027° 01.397 E, 258 m, April 2009 (RP 5).

3. Morchella vulgaris (Pers.) Boud.
Balıkesir, Burhaniye, Sübeylidere village; 39° 24.418 N - 027° 01.397 E, 258 m, April 2009 (RP 8, RP 9, RP 10).

Basidiomycetes

Agaricaceae Chevall.

4. Agaricus campestris L.
Balıkesir, Havran, Kobaklar village; 39° 33.396 N - 027°

Balıkesir, Havran, İnönü village, 39° 34.865 N - 027° 09.293 E, 235 m, November 2008 (RP 23).

**DISCUSSION**

In this study, 10 edible macrofungi taxa belonging to nine families, collected from Edremit Bay were reported and identified. Three of these belonged to Ascomycetes and seven to Basidiomycetes. Of those edible macrofungi taxa, 30% belonged to Ascomycetes, while 70% belonged to Basidiomycetes. Mushrooms are collected mainly at the mountain villages and are sold mainly at the local markets in the region. It is indeed a nutritional element and is a good income source for the local people. Identified species within this study were the *Morchella* sp. and *Gyromitra elata*; are the types which are collected during spring while there are other taxa collected during autumn. *Russula delica*, *Agaricus campestris*, *Morchella vulgaris*, *Morchella elata*, *Lactarius deliciosus*, *Tricholoma* sp. types are also collected at wide and sold at the local markets. Few people mentioned having identified *Ramaria aurea*, *Armillaria mellea*, *Gyromitra elata*, *Sparassis crispa* types in the region (Figure 2A to F). It was very rare that they were sold locally. According to the sources, *G. elata* is known as poisonous if consumed fresh, but still it was found that the locals consume it cooked.

Turkey has a large edible mushroom potential because it possesses favorable environmental conditions for the growth of mushrooms. Therefore, Turkey is becoming an important exporter for wild edible mushrooms (Demirbaş,
Mushrooms have long been a popular food in Turkey. Local people collect mushrooms for their own table and for sale. They recognize the benefit of the additional food, added flavor and the income from local sales and from export to Switzerland, Germany, and other countries. However, the nutritional value of these mushrooms has not been known and so that value has not been previously well appreciated (Çağlar Irmak et al., 2002).

2002). When compared, the results of this work showed similarities with the findings of the studies carried out in neighboring regions. The number of identical taxa and similarity percentages of neighboring studies are given in Table 2.

Edible mushrooms are sources of food and are delicious all over the world. They have a high nutritional value almost twice that of any vegetable or fruit. (Sivrikaya et al., 2002). Biochemical and statistical analyses showed that mushrooms have the crude protein, crude fibre, crude fat, carbohydrate, soluble sugars, ash and mineral elements (Moore and Chiu, 2001; Konuk et al., 2006; Liu et al., 2010). Edible mushrooms are highly valued as a good source of protein and their protein contents usually range from 14.0 to 44.3% of dry weight (Ragunathan et al., 2003; Sanmee et al., 2003; Konuk et al., 2006; Liu et al., 2010: Manjunathan and Kayiarasan, 2011). It was shown that the investigated mushrooms were rich sources of protein and carbohydrates and had low amounts of fat. (Konuk et al., 2006; Colak et al., 2009). The nutrient contents of the wild edible mushrooms are given in Table 3. In conclusion, wild edible mushrooms are an excellent food that can be used in a well-balanced diet for their low fat content, functional compounds and other nutritional values.

ACKNOWLEDGEMENTS

We wish to thank Prof. Dr. Mustafa İşloloğlu from the Muğla University, for helping in the descriptions of the edible macrofungi.
