Accepted 28 September, 2005

Acetone extracts of *C. woodii* leaf powder was separated by solvent-solvent partition into six fractions. The highest total activity was in the chloroform fraction. This fraction contained mainly one compound active against *S. aureus*. This compound was isolated by bioassay-guided fractionation using silica gel open column chromatography and identified by nuclear magnetic resonance (NMR) and mass spectroscopy (MS) as the stilbene 2′,3′,4-trihydroxyl-3,5,4′-trimethoxybibenzyl (combretastatin B5) previously isolated from the seeds of *C. kraussii*. It showed significant activity against *S. aureus* with an MIC of 16 μg/ml but with lower activity towards *P. aeruginosa* (125 μg/ml), *E. faecalis* (125 μg/ml) and slight activity against *E. coli*. This is the first report of the antimicrobial activity of combretastatin B5. Its concentration in the leaves was in the order of 5-10 mg/g which makes the use of non-polar leaf extracts a viable proposition in treating some infections, particularly in resource-poor settings.

Key words: Combretastatin B5, bibenzyl, stilbene, antibacterial, Combretaceae.

INTRODUCTION

With the increasing resistance of bacteria to antibiotics due to misuse and over prescription, there is a need to develop new antibiotics to delay or prevent the arrival of a post-antibiotic era (Leggadrio, 1995). Plants have been used for centuries to treat infectious diseases and present an obvious source of new antimicrobial compounds (Cowan, 1999). Thus far, there has been little success in developing new compounds from plants for use in the pharmaceutical industry, but more success in developing plant extracts to be used especially to treat skin infections is likely.

The Combretaceae is widely distributed in the tropical climes of Africa, South America and Asia (but not in Australia) and is an important resource in traditional medical practice. Species of the two main genera, *Combretum* and *Terminalia* have been used in the treatment of syphilis, abdominal pains, conjunctivitis, diarrhoea and toothache, among other ailments (Hutchings et al., 1996; Gelfand et al., 1985; Watt and Breyer-Brandwijk, 1962). Several species of *Combretum* have antibacterial activity (Eloff, 1999; Martini and Eloff, 1998; Martini et al., 2004a). Several compounds including flavonoids, phenanthrenes, stilbenes, cyclobutanes and triterpenoids have been isolated (Pettit et al., 1987a, 1987b, 1995; Rogers and Verotta, 1995; Katerere, 2001; Katerere et al., 2004; Martini et al., 2004b).

In a preliminary screening of 27 members of the Combretaceae, acetone leaf extracts of *C. woodii*, a deciduous tree found in northern South Africa and Swaziland had a reasonable antibacterial activity (Eloff, 1999). It contained antibacterial constituents that have different *Rf* values to the closely related species, *C. erythrophyllum* (unpublished results). More detailed investigation of *C. woodii* (Eloff et al., 2005) revealed that intermediate polarity extracts have substantial antibacterial activity against *Staphylococcus aureus*, *Pseudomonas aeruginosa*, *Escherichia coli* and *Enterococcus faecalis* with minimum inhibitory concentration (MIC) values in the order of 0.04 mg/ml. These activities were better than the two positive controls ampicillin and chloramphenicol. In many cases where antimicrobial compounds have been isolated, the compounds are present in low concentrations. In the acetone extracts of *C. woodii* one of the major

compounds was also the principal antibacterial compound against *S. aureus*. This compound also had a distinctive colour reaction with vanillin-sulphuric acid (Eloff et al., 2005) and it seemed appropriate to isolate and characterise it.

We report here for the first time the isolation of a stilbene, the main antibacterial compound from the leaves of *C. woodii*. Although the compound has been previously isolated from the seeds of *C. kraussii*, this is the first report of its presence in high concentrations in leaves and of its antibacterial activity.

**EXPERIMENTAL**

**Plant material**

Leaf material was collected from two trees growing in the Lowveld National Botanical Garden, Nelspruit, South Africa. The origin of each tree is recorded in the database of the botanical garden and a voucher specimen was deposited in the garden’s herbarium (Eloff, 1999).

**Analysis of extracts by TLC**

The following solvent systems were used to analyse fractions by thin layer chromatography (TLC) using Merck, Kieselgel 60 F254 plates : benzene : ethanol : ammonium hydroxide (BEA) (36:4:0.4), ethylacetate : methanol : water (EMW) (40:5:4.4) and chloroform : ethylacetate : formic acid (CEF) (20:16:4). Separated compounds were visualized by spraying with freshly prepared vanillin spray reagent (0.1 g vanillin, 28 ml methanol, 1 ml sulphuric acid) (Stahl, 1969). The plates were carefully heated at 105°C to optimal colour development.

**Extraction and preliminary fractionation**

Dried leaves (150 g) were milled into a fine powder with a Jankel and Kunkel model A10 mill and then extracted with acetone to yield 15.6 g. This was further fractionated using the solvent-solvent fractionation procedure recommended by the USA National Cancer Institute as described by Suffness and Douros (1979) and adapted by Eloff (1998a). This process leads to six fractions separated based on solubility characteristics of the constituents.

All extracts were then taken to dryness in a vacuum rotary evaporator and weighed. Extracts were reconstituted in appropriate solvent to make up stock solutions of 20 mg/ml. A 5 μl aliquot of each was loaded on TLC plates (Merck) that were developed using the eluent systems described above.

**Antibacterial activity**

The number of antibacterial compounds present was determined by bioautography using the method described by Begue and Kline (1972). The minimum inhibitory concentration (MIC) of fractions was determined by a serial dilution microplate assay using tetrazolium violet to indicate growth of the bacteria (Eloff, 1998b). Four organisms recommended by the National Committee for Clinical Laboratory Standards (NCCLS, 1992) as important causative agents of nosocomial infections were used. These were *Staphylococcus aureus* (ATCC 29213), *Pseudomonas aeruginosa* (ATCC 25922), *Escherichia coli* (ATCC 27833) and *Enterococcus faecalis* (ATCC21212). The MIC of the isolated compound was compared with reference antibiotics (ampicillin and chloramphenicol) as positive controls.

**Isolation by column chromatography**

About 4 g of the chloroform fraction, which had the highest total antibacterial activity, was applied to a Silica gel 60 (63-200 μm) (Merck) column and eluted with varying mixtures of chloroform and ethyl acetate. Eluted fractions were collected and allowed to concentrate under an air stream at room temperature and analysed by TLC and bioautography. Compound 1 was purified by recrystallization from a mixture of methanol and chloroform. 1H- and 13C-NMR spectra were obtained at Medical University of Southern Africa (Medunsa) on a 300 MHz Varian NMR machine (Oxford instruments). Mass spectrometric analysis (HREIMS) was performed on a VG70-SEQ instrument at Cape Technikon.

**RESULTS AND DISCUSSION**

Acetone extracted about 10 % (15.60 g) of starting plant material. In the group separation technique, the quantity partitioning into the various solvents was determined. The highest percentage went into hexane (32%) and chloroform (26%). Water and 35% water in methanol had the lowest percentage (Figure 2). This was similar to the result obtained in a previous study on *C. erythrophyllum* (Martini and Eloff, 1998).

We assayed the various fractions for antibacterial activity using bioautography (Figure 3) and the micro-titre assays described above. Most of the activity was in the chloroform and hexane fractions. These fractions showed the highest total activity, calculated by dividing the mass by the MIC value (Table 1) as suggested by Eloff (2000, 2004), against the four test bacteria. The aim was to isolate the main antibacterial compound with an Rf of 0.74 in EMW. Inspection of the bioautogram (Figure 3) shows that this compound was present in five of the fractions. There were also at least six other antibacterial compounds. The chloroform fraction had a relatively simple composition containing predominantly the main antibacterial compound. This compound was yellow in visible light, fluoresced purple-blue in 365 nm light and was maroon turning to brown later after treating with vanillin-sulphuric acid spray reagent. Column chromatography of the chloroform fraction as described above led to the successful isolation of this compound (1).

The structure of compound 1 (Figure 1) was elucidated by NMR and MS as the bibenzylic compound, 2’,3’,4’-trihydroxy-3,5,4’-trimethoxy bibenzyl (combretastatin B5) previously isolated from the seeds of *C. kraussii* (Pellizzoni et al., 1992). HREI-MS gave a molecular ion at m/z 320 corresponding to C17H22O5 and only two major fragments at m/z 153 (C6H2O3) and 167 (C7H17O5). This is typical of tropolium derivatives associated with bibenzylic compounds (Letcher et al., 1972; Katerere, 2001). The fragmentation pattern was also suggestive of dihydroxy-

Figure 1. Structure of compound 1 (2',3',4-trihydroxyl-3,5,4'-trimethoxy bibenzyl, combretastatin B5).

methoxy functions on one aromatic ring and dimethoxyhydroxy moieties on the second. The ¹H-NMR spectra showed aromatic protons at 6.5 ppm (1H, d, J = 8.4 Hz) and 6.36 ppm (1H, d, J = 8.4 Hz) which are ortho coupled as well as the 2-proton singlet at 6.4 ppm. There is also a signal at 3.84 ppm integrating to three methoxyl groups and a complex multiplet at 2.82 ppm which is typical of the ethane bridge in bibenzylic compounds (Majumder et al., 1999; Katerere, 2001). By comparison with the literature and 2-D NMR, compound 1 was found to be 2',3',4-trihydroxy-3,5,4'-trimethoxy bibenzyl (combretastatin B5). Though previously isolated from the seed of *C. kraussi* (Pellizzoni et al., 1992), this is the first report of its presence in plant leaves.

Compound 1 had an *in vitro* antibacterial activity against all the four test organisms that compared favourably with ampicillin and chloramphenicol. *S. aureus* was the most sensitive of all the test organisms with an MIC value of 16 µg/ml followed by *E. faecalis* (125 µg/ml) and *P. aeruginosa* (125 µg/ml) and *E. coli* (250 µg/ml) (Table 2). This makes the compound a potent agent.
against *S. aureus* with potential clinical application. Derivatives have been previously shown to possess potent anti-mitotic activity (Pellizzoni et al., 1992). There are no previous reports of its antibacterial activity.

Combretastatin B5 had a relatively low activity against *E. faecalis*, although the chloroform fraction was three times more active against *E. faecalis* than against *S. aureus* (Table 2). This can only be explained if other antibacterial compounds present in the chloroform extract had substantial activity against *E. faecalis* or if there were synergistic effects with other compounds that were removed on purification of combretastatin B5. The MIC of the pure compound towards *S. aureus* was 16 μg/ml. The MIC of the crude acetone extract was 310 μg/ml. This represents a c. 20-fold increase in potency with purification. The crude extract represented 100 mg/g leaf powder. From this it follows that, if there is only one antibacterial compound active towards *S. aureus* in the acetone extract, the concentration of combretastatin B5 should be 100/20 i.e. c. 5 mg/g leaf powder. With the inherent inaccuracy of the two-fold serial dilution assay there could be a doubling or halving of this value. Another way of roughly calculating the concentration in leaf material is to judge the concentration when 50 μg of crude extract was separated by TLC. When we separated different masses of CB5 in the same volume (5 μl), the size of the CB5 band in the crude extract was equivalent to c. 5 μg of the pure compound. Because 50 μg of the crude extract was chromatographed (5 μl of 100 mg/ml), it means that the concentration was c. 100 x 5/50 i.e. c. 10 mg/g. This very high concentration makes the use of extracts for clinical purposes a viable possibility particularly in poor communities.

**Figure 3.** Chromatogram and bioautogram of acetone extract of *C. woodii* leaves separated into different fractions by solvent-solvent extraction. TLC plate developed in EMW sprayed with vanillin-sulphuric acid [left] and with *S. aureus* culture incubated overnight and then sprayed with INT [right]. Growth inhibition indicated by clearing zones on TLC plate. Lanes from left to right: hexane (H), chloroform (CHCl₃), carbon tetrachloride (CCl₄), 35% water in methanol (35% w/m), butanol (B) and water (W) fractions.

### Summary of spectroscopic data

2',3',4-trihydroxy-3,5,4'-trimethoxy bibenzyl (combretastatin B5), C₁₇H₂₀O₆ (1). Yellow amorphous solid; 'H-NMR (300 MHz, CDCl₃) 6.40 (2H, s), 6.54 (1H, d, J 8.4 ), 6.35, (1H, d, J 8.4), 3.84 (9H, s), 2.82 (2H, m) ¹³C-NMR (75 MHz, CDCl₃): 133.4 (C-1), 105.1 (C-2),
146.8 (C-3), 132.2 (C-4), 146.8 (C-5), 105.1 (C-6), 36.5 (C-1a), 32.1 (C-1'), 121.5 (C-1''), 142.1 (C-2), 132.7 (C-3), 145.2 (C-4'), 102.3 (C-5'), 120.1 (C-6'), 56.2 (3,5-OMe), 56.1 (4'-OMe). HREIMS m/z (rel. int.): 320 [M]+(41%), 153 [M-C6H1O3]+ (100%), 167 [M-C6H2O3]+

CONCLUSION

The leaves of *C. woodii* contain several antibacterial compounds of which the major compound active against *S. aureus* was isolated and characterized. This compound, though reported elsewhere previously, was isolated from the leaves of *Combretum* spp. for the first time and its potent antibacterial activity noted here for the first time. Further work should be directed towards testing the toxicity of CB5, expanding the assay to other micro-organisms and possible pre-clinical development.

The high concentration of this compound in leaves also make the use of leaf extracts a viable possibility. These results partly validate the ethnobotanical use of many *Combretum* species for conditions that may be of bacterial aetiology. *C. woodii* extracts also contain other antibacterial compounds with high antibacterial activity against *Escherichia coli*, *Pseudomonas aeruginosa* and *Enterococcus faecalis* (Eloff et al., 2005). This warrants further investigation of these extracts.
