Received 4 March, 2017; Accepted 16 May, 2017

Ranches of Mexico’s southeast region have an important energetic potential on their organic waste that remains unexploited. The objective of this work is to present the construction and operation of a floating dome “Biodigester” in a ranch located in Jalapa, Tabasco, Mexico, in addition to the analysis of produced biogas and its electric energy generation. The construction was based in the specifications of a Puxin® biogas plant. The biogas was analyzed using infra-red spectrometry with Fourier transforms. Electric energy was generated using an Energetic® motor-generator. The methane and carbon dioxide percentage at 90 days of hydraulic retention time (HRT) was 51.51 and 29.05%, respectively. The electric energy generation was 3.58 kWh m⁻³.

Key words: Biomass, floating dome, energy, biodigestate, biogas.

INTRODUCTION

In developing countries, particularly India and China, animal manure is used by farmers and the dairy industry to produce biogas, before manure is subject to other uses, such as fertilizers mostly. Anaerobic digestion is a biochemical process for organic matter degradation, by action of microorganisms under anaerobic conditions, resulting in products satisfying important needs of rural zones, such as biogas. Biogas for its heat potential and power generation, and digestate with a high content of nutrients applicable to crops (Asankulova, 2008; El-Mashad and Zhang, 2010; Fantozzi and Buratti, 2009; Fernández et al., 2010; Ferrer et al., 2011; Meng and Chung, 2010). In tropical zones, substrata with the highest potential for biogas production are water hyacinth (Eichhornia crassipes), manure (cattle, sheep, pork and poultry), cow gastric rumen content, yucca leaves, urban solid waste, agricultural wastes and residual water (Arthur et al., 2011; Krishna et al., 1991). Arthur et al. (2011) mention that sheep manure yield a return of 0.04 m³ kg⁻¹ manure. Akbulut (2012) reports the generation of...
5.5 kWh m$^{-3}$, biogas quality was 55% of CH$_4$, yielding with cow manure in combination with sheep manure (93.9 and 6.01%, accordingly). Aburas et al. (1996) state that biogas plants are more feasible in agricultural farms or ranch, particularly for isolated rural zones, away from the commercial electric networks, since they supply power for activities such cooking, heating and power generation. The also mention that a regular farm of approximately 2.3 ha (170 dairy cows, 20 veils and 2 bulls) have a daily requirement for light and motors consumption (water and charge) of 32.73 kWh$^{-1}$, which may be supplied by 5 m$^3$ of biogas, with a 67% content of methane, in a 16 m$^3$ plant, and a production of 3.2 m$^3$ day$^{-1}$ of biogas. Mohseni et al. (2012) report that biogas is considered as a first generation fuel, because of the simplicity of the process to producing it, without specific chemical processes. What makes it attractive to users of this type of technology is its easy operation and maintenance, because there are very expensive and complex biogas plants, which are being rejected in rural zones. Arthur et al. (2011) stated that Puxin® biogas plant is a pressure digester and hydraulic seal, build with concrete and used in rural regions of India, where it has been widely accepted. A common activity in Mexico's southeast ranches is to improperly dispose organic waste which causes water, soil and air pollution.

In Mexico's southeast, the construction of anaerobic biodigester is a practice that is just beginning to be developed. This work presents the construction and operation of a floating dome "Biodigester" in a ranch located in Mexico's southeast, in addition to the analysis of produced biogas and its electric energy generation, which offers a sustainable option for farmers to dispose organic waste.

MATERIALS AND METHODS

Biodigester construction

Puxin® adapted biogas plant is described in Figure 1. To build the 10 m$^3$ Puxin® biogas plant, the following activities were performed:

Prospective view

A visit to “El Rodeo”, a ranch located in the municipality of Jalapa, in Tabasco, Mexico, was made to define, based on the land topography project functionality, the area where the biogas plant was built.

Site suitability

Works of site cleaning, stroke and leveling were completed. Later on an excavation of 4.00 × 4.00 × 3.00 m was made.

Reactor construction

A simple concrete base was built to receive the Biodigester structure: Before starting with the construction of the biogas plan, a F’c = 100 kg cm$^{-2}$ concrete base was built with the purpose of isolating the foundation area from mud and water puddles, which may contaminate concrete when pouring it for the biodigester base.

Pouring biodigester structure:

1. Lenticular slab: An important part of the structure. From this section depends the structure works as a whole in a stable form. It is circular, 3.00 m in diameter. It was made out of F’c = 250 kgcm$^{-2}$ concrete and reinforced with 6-6/4-4" electro-welded steel mesh.

![Figure 1. Adapted Puxin® biogas plant. (1) Mixer or Equalizer; (2) Inlet register; (3) Stomach or reactor; (4) Biogas reservoir; (5) Outlet register; (6) Neck; (7) Biogas outlet; (8) Biodigestate reception cell.](image-url)
3/8” steel bars were placed all around the perimeter, with 20 cm² separation with the “stomach and shoulder”. The purpose of the steel bar is to join monolithically the slab, stomach, and shoulder (Figure 1).

2. Stomach and shoulder: The wood frame was set to hand the “stomach and shoulder”. Vegetable oil was used to facilitate separation. Inside the “stomach” wood frame, 3/8” steel bars were placed every 20 cm on the perimeter of the slab, in square shape (90°), with the purpose of tying together both sides of the biodigester (slab and stomach). The stomach and shoulder structure was built with Fc = 250 kg/cm² concrete and reinforced with 6-6/4-4” electro-welded steel mesh. The final structure was built monolithically (Figure 2).

3. Neck: A wood frame was prepared to build the neck. Fc = 250 kg/cm² concrete and reinforced with 6-6/4-4” electro-welded steel mesh was used, and was monolithically poured. On the top section of this structure, a flange was made to receive the dome that shall be the biodigester cap. (Figure 3).

4. Input and output of registers: On the biodigester shoulder, two 6” PVC tubes were attached in symmetric line, which shall be used as structures for feeding and releasing the biodigestate. Input and output tubes were cut at a length of 1.50 m and were placed with a separation of 0.50 m from the bottom of the biodigester. The measures of the inlet and outlet are 1.00 × 0.80 m, block walls, matching its height at neck level.

5. Biogas plant finishing works: For internal finishing plaster of stomach and shoulder, a 1:12:1 mix (cement, sand and water respectively) was used. Once constructions activities of the biodigester were completed, soil from excavation was spread and flattened to field natural level.

6. Biodigestate reception cell: At output register, a pipe was adapted to lead “digestate” through a syphon to a digested liquids reception tank, with measurements 3.22 × 1.67 × 1.24 m and a volume of 5.31 m³. This particular system automatically sends exceeding liquids to a reception cell by means of gravity.

7. Mixer: A devise measuring 1.00 × 1.00 × 1.00 m and a volume of 1 m³ was built, with the purpose of mixing upstream substrata.

It is worth mentioning that structure reinforcement, implementation of the digestate reception tank and the uses of higher Fc were adaptations made during the construction of the biodigester.

**Glass fiber dome:** The dome used was fiber glass based with 6 mm thickness. It also counts with a 1” PVC biogas outlet. Three metal structures of a triangular shape were place in the basement, and triangular metal supports placed over the circumference of the dome base, in order to keep it suspended while gathering the biogas.

Figure 3. Operation phase. (1) Feeding; (2) Placement of Dome; (3) Utilization of biogas.
Biodegester operation
A total of 160 kg of substrata were introduced in the mixer (120 kg of sheep manure and 40 kg of aquatic fern (Salvinia molesta)). Forty liters of residual sludge from fish tanks as inoculum, plus more than 9800 L of water from a deep well (organic load rate of 11.14 kg SV m\(^{-3}\) day\(^{-1}\)) (Figure 1). This mix was sent by gravity to the input register, slowly filling the stomach and the neck. The biogas outlet was intentionally left open to avoid the formation of air bubbles under the dome (Figure 2). Hydraulic retention time (HRT) exceeded 90 days. The first time the dome was fully filled with biogas, it was used in a Puxin® stove (Figure 3).

Substrata analysis
Humidity was determined (SCFI, 1985); total solids were calculated from the difference of 100% humidity (Mahar et al., 2012), volatile solids (SCFI, 2015) and ashes (SCFI, 1984). Also, the elemental analysis of carbon, hydrogen, oxygen, nitrogen and sulfur (Analyzer Perkin Elmer® model: PE 2400). The chemical equation for sheep excreta and water fern was calculated.

Biogas analysis
From the start date of the project, an analysis of generated biogas was completed every week in a 5 cm length gas cell with KBr windows, using the “transmittance” technique, in a Thermo Nicolet (Nexus 670-FTIR) spectrometer, equipped with a Deuterated Triglycine Sulfate (DTGS) detector. Spectrums of 64 sweeps average were gathered for each sample, at a spectral resolution of 4 cm\(^{-1}\), between 400 and 4000 cm\(^{-1}\)intervals.

Biodigestate analysis
For the biodigestate, a Hanna® 9828 equipment was used to measure oxygen dissolved, pH, temperature atmospheric pressure, resistivity, conductivity, true conductivity, total dissolved solids, salinity, oxide reduction potential (REDOX) and oxygen dissolved (% of saturation) in the field; and in the laboratory, nitrogen, phosphor and potassium were measure with a HANNA® HI83225 equipment, as well as the chemical oxygen demand (COD) from the beginning to the end, with a HANNA® C99 equipment.

Electric energy generation
The theoretical estimation of electric energy generated was calculated based on the amounts of biogas produced by each substrata used. For this purpose the Akbulut (2012) and Dach et al. (2014) equations were adapted as follows:

\[
E_{\text{Electric}} = (\text{total amount of biogas, m}^3) \times (% \text{ Efficiency}) \times \left( \frac{\text{Yield, kWh}}{\text{m}^3} \right)
\]

An Energetic® power generation equipment was used, with a generation capacity of 4.2 kWh m\(^{-3}\) (Figure 4). A theoretical efficiency of 42% was taken, as reported by Dach et al. (2014).

RESULTS
Table 1 shows the substrata analysis of sheep manure and aquatic fern used in the process. Table 2 shows the values for carbon, hydrogen, oxygen, nitrogen and sulfur, as well as it chemical formula, anaerobic reaction and energy potential for sheep manure and aquatic fern.

An estimate of the total biogas generation was made with both substrata, and results are described in Table 3.

Figure 5 shows infra-red spectrum of biogas from sheep manure, aquatic fern and residual sludge in fish tanks generated at the floating dome type plant located at “El Rodeo” ranch.

shown of 667 cm\(^{-1}\) assigned to a deformation out of the plane and deformation in the plane at the same frequency. It is also observed in the spectra two double bands in the region of 3550 to 3750 cm\(^{-1}\) which correspond to primary alcohols -CH\(_2\)OH and secondary alcohols =CHOH.

In the Table 4, are shown group frequencies for principal gases in the biogas. Table 5 shows the percent composition of CH\(_4\), CO\(_2\), NH\(_3\), CHO\(_H\) and CH\(_2\)OH calculated based on the intensities of the absorbance bands. Each percentage concentration resulted from the ratio of the absorbance of each band divided by the total absorbance of all interferogram bands. Figure 6 shows how the methane values increase as the hydraulic retention time increases and the carbon dioxide values decrease as time passes.

Table 5 shows average values with their corresponding standard deviation of physicochemical parameters of biodiggeste, measured in field and in laboratory.

Electric generation was determined from the generated theoretical biogas total value, 1.00 m\(^3\), applying the following equation:

\[
E_{Electric} = (1.00 \text{ m}^3) \times (0.42) \times \left( \frac{4.2 \text{ kWh}}{\text{m}^3} \right) = 1.76 \text{ kWh}
\]

After completing pilot tests using the electric generator, it was possible to achieve the generation of 110 and 220 V of energy, for 51.21 min, using 1 m\(^3\) of biogas (Table 7). The total generation of electric power was 3.58 kWh. Figure 7 shows the use of energy to start a power drill.
DISCUSSION

The organic load rate is much higher than the range reported by Álvarez and Lidén (2009) of 4 and 6 kg of SV m$^{-3}$ day$^{-1}$, however, the methane yield of 0.399 is higher than the range of 0.7 to 0.14 m$^3$ kg$^{-1}$ SV.

Regardless the season of the year, as Kalia and Kanwar (1998), Cantrell et al. (2008) mention, methanogen biogas production rate is sensitive to changes in influence material, pH, temperature, organic load velocity and hydraulic retention time (HRT), and they shall be controlled with the objective of maximizing the same biogas production.

Average temperature of the plant was always lower than environment temperature, as reported by Kalia and Kanwar (1998).

Mohammed et al. (2013) mention that organic compost from animals, is mostly treated by anaerobic digestion for

energy production, and it is a product that may benefit farmers in different manners.

The FTIR provided reasonable precision with a root mean square error of 10% using partial least squares analysis (Hepburn et al., 2015).

Conclusions

A Puxin® adapted biogas plant, floating dome type works for the southeast of Mexico. The mixes of substrata used represent a new opportunity for energy conversion when treating livestock wastes for a benefitted center (Cantrell et al., 2008). A floating dome has been redesigned and a new element has been included for biodiggestate gathering (reception cell), along with the modification in material proportions. It is important to continue working in the reduction of the hydraulic retention time (HRT) as Cantrell et al. (2008) mentions. Other substrata generated in farms must be considered. And also assess the technology using for instance the analytical hierarchical process, appointed by Rao et al. (2014). Muller et al. (2007) which mentions that taking biofuel at a farm scale offers a great opportunity for the agricultural sector to reduce their dependency from imported fossil fuels, and at the same time, soil, water and air quality improve. According to Mohammed et al. (2013) the (%) of biomass contribution rate around the world for a final energy consumption, where Latin America is positioned in an intermediate place with a 18.20%, in comparison with Africa (60%) and the Middle East (0.30%), showing that agricultural biomass exploitation is not properly used and must be supported by government and other interested parties, through a pertinent program of support and incentive provisions specifically for transferring the focus on resources such as forestry for other bio-energy wastes. Our current study indicates that we can use the mix of substrata; however, improvement in biogas quality and production is highly desirable, therefore further studies about different mix of substrate will be made. In addition, longer-term examinations will be continued on the efficacy of the best process to enrich the biogas and to produce electric energy.
