This Paper deals with calculating the minimal and maximal shares of individuals or organizations based on different criteria. Suppose that players are selfish and the score for each criterion for a player is an interval. Each player makes any possible efforts to bring about his or her ideal condition. In this paper a new scheme to calculate the minimal allocated cost and the maximal allocated benefit for interval data is offered. In this scheme also the new models have been proposed for avoiding zero weight occurrence. Here ultimate allocated is achieved for each player with suitable coalition within several defined coalition.

Key words: Data envelopment analysis (DEA), game theory, and assurance region method.

INTRODUCTION

Consider $n$ players each have $m$ criteria for evaluating their competency or ability, which is represented by interval. For example, consider a usual classroom examination, the higher score for a criterion is, the better player is judged to perform that criterion. For example let the players be three students A, B and C, with three criteria, linear algebra, real analysis and numerical analysis are supposed to be variable in an interval. Now the problem is allocated a certain amount of fellowship in accordance to their score at these three criteria. All players are supposed to be selfish in the sense that they insist on their own advantage on the scores. However, they must reach a consensus in order to get the fellowship. This paper with using allocating and imputing the given benefit (Jahanshahloo et al., 2006) propose a new scheme for compute maximal allocated benefit and minimal allocated cost for players under the framework of game theory and data envelopment analysis (DEA) (Cooper et al. 2000). By this scheme the zero weight occurrence can be avoided. It also applies to determining the coalition with the ultimate benefit and least cost. The sections of this paper are as follows. In next sections, first the basic models are described and some properties of problem are proved, then extension of the basic model and introduce coalitions are discussed. Finally after a numerical example, conclusions and some remarks are present.

BASIC MODELS OF THE GAME

We introduce the basic models and structures of the game based on Nakabayashi and Tone (2006).

Selfish behavior

Let $[x_i^1, x_i^u]$ be the score of player $j$ in the criterion $i$, for $i = 1, \ldots, m$ and $j = 1, \ldots, n$ and $x_i^1 > 0, x_i^u > 0$. It is assumed that the higher the interval score for a criterion is, the better player is judged to perform as regard to that criterion. Each person $k$ has a right to choose two sets of nonnegative weights $w^k = (w_i^k, \ldots, w_m^k)$ to the criteria that are most preferable to the player. Using the weight $w^k$, the relative scores of player $k$ to the total score are defined as follows:

*Corresponding author. E-mail: mojtaba.ramezani.53@gmail.com.
\[ \sum_{i=1}^{m} w_i x_i^1 - \sum_{i=1}^{m} w_i x_i^n \sum_{i=1}^{m} \left( \frac{c_i(k)}{w_i} \right) \]

The denominator represents the total score of all players as measured by player \( k \) weight selection. While the numerators indicate player \( k \) self-evaluation as a lower and upper bound lower bound. Therefore, the statement (1) represents player \( k \) lower and upper relative importance in accordance to the \( x_i^1, x_i^n \). We assume that the weighted scores are transferable. Player \( k \) wishes to maximize this ratio by selecting the most preferable weights \( w_k \), for each of \( x_i^1, x_i^n \) as follows:

\[
\text{Max} \quad \frac{\sum_{i=1}^{m} w_i x_i^1}{\sum_{i=1}^{m} w_i x_i^n} \quad \text{s.t.} \quad w_i \geq 0 \quad (\forall i)
\]

The inequality above follows from \( \sum_{i=1}^{m} x_i^1 = 1 \) and \( \sum_{i=1}^{m} x_i^n = 1 \) (Charne's et al., 1978). We divide the row \( (x_i^1, ..., x_i^n) \) by the row-sum

\[
\sum_{i=1}^{m} \left( x_i^1 + x_i^n \right) = 1, i = 1, ..., m
\]

Thus, using the Charnes-Cooper transformation scheme, the fractional programs (2) and (3) can be expressed using a linear programs follows:

\[
c_i^1(k) = \text{Max} \sum_{i=1}^{m} w_i x_i^1 \quad \text{s.t.} \quad \sum_{i=1}^{m} w_i = 1 \quad w_i \geq 0 \quad (\forall i)
\]

After solving problems (5) and (6), if the optimal value of the problem (5) and (6) are \( c_i^1(k) \) and \( c_i^n(k) \) respectively, then \( c_i^1(k) + c_i^n(k) \) may be considered as optimal value of the problem. Now the problem is to maximize the objectives (5) and (6) on the simplex \( \sum_{i=1}^{m} w_i = 1 \).

Apparently, the optimal solution is given by assigning 1 to \( w_i^k \) and \( w_i^{k'} \) for the criterion \( i(k) \) and \( i(k') \) such that \( x_i^{k} = \text{Max} \{ x_i^1 | i = 1, ..., m \} \) and \( x_i^{k'} = \text{Max} \{ x_i^n | i = 1, ..., m \} \) respectively. Therefore, the optimal values will be as follows: ning 0 to the weight of remaining criteria. We denote this optimal value by \( c(k) \).

\[
c_i^1(k) = x_i^1 \quad \text{and} \quad c_i^n(k) = x_i^n \quad \forall i
\]

\[
\sum_{i=1}^{m} c_i^1(k) + c_i^n(k) \geq 1
\]

\[
\text{Theorem 1}
\]

\[
\text{Proof}
\]

Let the optimal weight for player \( k \) be \( w_i^p = (w_i^{p_1}, ..., w_i^{p_m}) \) and \( w_i^n = (w_i^{n_1}, ..., w_i^{n_m}) \) \( \sum_{k=1}^{m} w_i^p = 1 \) and \( \sum_{k=1}^{m} w_i^n = 0 \). Then we have

\[
\sum_{i=1}^{m} c_i^1(k) + c_i^n(k) = \sum_{i=1}^{m} c_i^1(k) + \sum_{i=1}^{m} c_i^n(k) = \sum_{i=1}^{m} w_i^p x_i^1 + \sum_{i=1}^{m} w_i^n x_i^n = \sum_{i=1}^{m} x_i^1 + \sum_{i=1}^{m} x_i^n = 1
\]

The inequality above follows from \( x_i^1 \geq x_i^1 \) and \( x_i^n \geq x_i^n \) and the last equality follows from the row-wise normalization. This theorem assert that, if each player sticks to his egoistic sense of value and insists on getting the portion of the benefit as designated by \( c_i^1(k) \) and \( c_i^n(k) \), the sum of shares usually exceeds 1 and hence \( c_i^1(k) + c_i^n(k) \) cannot fulfill the role of division of
the benefit. If eventually the sum of $c^1(k)$ and $c^*(k)$ turns out to be 1, all players will agree to accept the division $c^1(k) + c^*(k)$, since this is obtained by the players most preferable weight selection. The latter case will occur when all players have the same and common optimal weight selection, we have the following theorem.

**Theorem 2**

The equality $\sum_{k=1}^{n} c^1(k) + c^*(k) = 1$ holds if and only if our data satisfies the condition $x_{11}^1 = x_{12}^1 = \ldots = x_{1m}^1$ and $x_{11}^a = x_{12}^a = \ldots = x_{1m}^a \quad \forall k = 1, \ldots, n$. That is, each player has the same score with respect to the $m$ criteria.

**Proof**

The (if) part can be seen as follows. Since $c^1(k) = x_{11}^1$ and $c^*(k) = x_{11}^a$ for all $k$, we have:

$$\sum_{k=1}^{n} c^1(k) + c^*(k) = \sum_{k=1}^{n} c^1(k) + \sum_{k=1}^{n} c^*(k) = \sum_{k=1}^{n} x_{11}^1 + \sum_{k=1}^{n} x_{11}^a = 1$$

The (only if) part can be proved as follows. Suppose $x_{11}^1 > x_{12}^1$ and $x_{11}^a > x_{12}^a$, then there must be column $h \neq 1$ and $h' \neq 1$ such that $x_{11}^1 < x_{12}^1$ and $x_{11}^a < x_{12}^a$, otherwise the second row sum cannot attain 1. Thus we have $c^1(h) \geq x_{12}^i, c^*(h') \geq x_{12}^i$, and $c^1(j) \geq x_{12}^i (\forall j \neq h), c^*(j) \geq x_{12}^i (\forall j \neq h')$. Hence it holds that

$$\sum_{k=1}^{n} c^1(k) + c^*(k) = \sum_{k=1}^{n} c^1(k) + \sum_{k=1}^{n} c^*(k) \geq \sum_{j=1}^{n} x_{12}^i + \sum_{k=1}^{n} x_{12}^i$$

$$+ \sum_{j=1}^{n} x_{12}^i > \sum_{j=1}^{n} x_{12}^i + \sum_{j=1}^{n} x_{12}^i = 1$$

This leads to a contradiction. Therefore player 1 must have the same score in all criteria. The same relation must hold for the other players. In the above case, only one criterion is needed for describing the game and the division proportional to this score is a fair division.

However, such situation might occur only in rare instances. In the majority of cases, we have

$$\sum_{k=1}^{n} c^1(k) + c^*(k) > 1.$$
\[ c^\ast(S \cup T) = \max \sum_{i=1}^{n} x_i^1 + \max \sum_{j=1}^{m} x_j^s \leq \max \sum_{i=1}^{n} x_i^1 + \\max \sum_{j=1}^{m} x_j^s \]

\[ = c^\ast(S) + c^\ast(T) + c^\ast(S) + c^\ast(T) \]

**Theorem 4**

\[ c^\ast(N) + c^\ast(N) = 1 \]

**Proof**

\[ \sum_{i=1}^{n} w_i \cdot \sum_{j=1}^{m} x_i^1 = 1 \]

A DEA minimum game

The opposite side of the game can be constructed by \((N,d)\) as follows:

\[ d^\ast(k) = \min \sum_{j=1}^{m} w_j \cdot x_j^s \]

\[ s.t. \sum_{i=1}^{n} w_i = 1 \]

\[ w_i \geq 0 \; \forall i \]

\[ d^\ast(k) = \min \sum_{j=1}^{m} w_j \cdot x_j^s \]

\[ s.t. \sum_{i=1}^{n} w_i = 1 \]

\[ w_i \geq 0 \; \forall i \]

Thus these game start from \(d^\ast(k) > 0\) and \(d^\ast(k) > 0\) and enlarges the gains by the coalition until the grand coalition \(N\) is reached.

**Theorem 5**

\[ \sum_{i=1}^{n} d^\ast(k) + d^\ast(k) \leq 1 \]

Analogously to the max game, for the coalition \(S \subseteq N\), we define

\[ d^\ast(S) = \min \sum_{i=1}^{n} w_i \cdot x_i^1 \]

\[ s.t. \sum_{i=1}^{n} w_i = 1 \]

\[ w_i \geq 0 \; \forall i \]

\[ d^\ast(S) = \min \sum_{i=1}^{n} w_i \cdot x_i^1(S) \]

\[ s.t. \sum_{i=1}^{n} w_i = 1 \]

\[ w_i \geq 0 \; \forall i \]

\[ d^\ast(S) = \min \sum_{i=1}^{n} w_i \cdot x_i^1(S) \]

\[ s.t. \sum_{i=1}^{n} w_i = 1 \]

\[ w_i \geq 0 \; \forall i \]

**Theorem 6**

The min game \((N,d)\) is super - additive we have

\[ d^\ast(S \cup T) + d^\ast(S \cup T) \geq d^\ast(S) + d^\ast(T) \]

for each \(S, T \subseteq N\) with \(S \cap T = \emptyset\)

**Proof**

By renumbering the indexes, we have \(S = \{1,\ldots,h\}\). \(S = \{h+1,\ldots,k\}\) and \(S \cup T = \{1,\ldots,k\}\). For these sets it holds that

\[ d^\ast(S \cup T) + d^\ast(S \cup T) \]

\[ = \min \sum_{i=1}^{n} x_i^1 + \min \sum_{j=1}^{m} x_j^s \geq \min \sum_{i=1}^{n} x_i^1 \]

\[ + \min \sum_{j=1}^{m} x_j^s + \min \sum_{j=1}^{m} x_j^u \]

\[ = d^\ast(S) + d^\ast(T) + d^\ast(S) + d^\ast(T) \]

Thus these game start from \(d^\ast(k) > 0\) and \(d^\ast(k) > 0\) and enlarges the gains by the coalition until the grand coalition \(N\) with \(c^\ast(N) + c^\ast(N) = 1\) is reached.

**Theorem 7**

\[ d^\ast(S) + d^\ast(S) + c^\ast(N \setminus S) + c^\ast(N \setminus S) = 1 \forall S \subset N \]

**Proof**

By renumbering the indexes, we can assume that \(S = \{1,\ldots,h\}\), \(N = \{1,\ldots,n\}\) and \(N \setminus S = \{h+1,\ldots,n\}\). For these sets, it holds that

\[ d^\ast(S) + d^\ast(S) + c^\ast(N \setminus S) + c^\ast(N \setminus S) \]

\[ = \min \sum_{i=1}^{n} x_i^1 + \max \sum_{j=1}^{m} x_j^s \]

\[ + \max \sum_{j=1}^{m} x_j^1 + \max \sum_{j=1}^{m} x_j^u \]
EXTENSIONS

In this section, we extend basic model to maximal allocated benefit and minimal allocated cost for interval data and discuss the zero weight.

Maximal allocated benefit

Suppose that there are s criteria for representing benefits. Let \([y^1_i, y^u_i](i = 1, ..., s)\) be the benefits of player \(j (j = 1, ..., n)\) where \(u_1, ..., u_s\) is the virtual weights for benefits. Analogous to the expression (1) we define the relative score of player \(j\) to the total scores as:

\[
\frac{\sum_{i=1}^{s} u_i y^1_i}{\sum_{i=1}^{s} u_i \left( \sum_{j=1}^{n} (y^1_j + y^u_j) \right)}
\]

(17)

\[
\frac{\sum_{i=1}^{s} u_i y^u_i}{\sum_{i=1}^{s} u_i \left( \sum_{j=1}^{n} (y^1_j + y^u_j) \right)}
\]

(18)

Player \(j\) wishes to maximize his benefits. We can express this situation by linear programs below:

Max \[\sum_{i=1}^{s} u_i y^1_i\]

s.t. \[\sum_{i=1}^{s} u_i \left( \sum_{j=1}^{n} y^1_j \right) = 1\]

\[\sum_{i=1}^{s} u_i y^1_i \geq 0 \quad (j = 1, ..., n)\]

\[u_i \geq 0 \quad \forall i\]

(19)

\[
\text{Max } \sum_{i=1}^{s} u_i \sum_{j=1}^{n} y^u_i
\]

s.t. \[\sum_{i=1}^{s} u_i \left( \sum_{j=1}^{n} y^u_j \right) = 1\]

\[\sum_{i=1}^{s} u_i y^u_i \geq 0 \quad (j = 1, ..., n)\]

\[u_i \geq 0 \quad \forall i\]

(20)

The weights of benefits are nonnegative. A characteristic function of the coalition \(S\) is defined by the linear program:

\[
c^1(S) = \text{Max } \sum_{i=1}^{s} u_i \sum_{j \in S} y^1_j
\]

s.t. \[\sum_{i=1}^{s} u_i \left( \sum_{j \in S} y^1_j \right) = 1\]

\[\sum_{i=1}^{s} u_i y^1_i \geq 0 \quad (j = 1, ..., n)\]

\[u_i \geq 0 \quad \forall i\]

(21)

\[
c^u(S) = \text{Max } \sum_{i=1}^{s} u_i \sum_{j \in S} y^u_j
\]

s.t. \[\sum_{i=1}^{s} u_i \left( \sum_{j \in S} y^u_j \right) = 1\]

\[\sum_{i=1}^{s} u_i y^u_i \geq 0 \quad (j = 1, ..., n)\]

\[u_i \geq 0 \quad \forall i\]

(22)

In the program (18), (19) the benefits of all players are nonnegative. Since the constraints of program (18) and (19) are the same for all coalitions, we have the following theorem.

Theorem 8

The maximal allocated benefits game satisfies a subadditive property.

Proof

For any \(S \subset N\) and \(T \subset N\) with \(S \cap T = \emptyset\), we have:
\[
\begin{align*}
&c^i(S \cup T) + c^c(S \cup T) \\
&= \text{Max} \sum_{i=1}^{n} u_i \sum_{j \in S} y^i_j + \text{Max} \sum_{i=1}^{n} u_i \sum_{j \in T} y^i_j \\
&= \text{Max} \left( \sum_{i=1}^{n} u_i \left( \sum_{j \in S} y^i_j + \sum_{j \in T} y^i_j \right) \right) \\
&\quad + \text{Max} \left( \sum_{i=1}^{n} u_i \left( \sum_{j \in T} y^i_j + \sum_{j \in S} y^i_j \right) \right) \\
&= \text{Max} \left( \sum_{i=1}^{n} u_i \sum_{j \in S} y^i_j + (\sum_{i=1}^{n} u_i \sum_{j \in T} y^i_j) \right) \\
&\quad + \text{Max} \left( \sum_{i=1}^{n} u_i \sum_{j \in T} y^i_j + (\sum_{i=1}^{n} u_i \sum_{j \in S} y^i_j) \right) \\
&\leq \text{Max} \sum_{i=1}^{n} u_i \sum_{j \in S} y^i_j + \text{Max} \sum_{i=1}^{n} u_i \sum_{j \in T} y^i_j \\
&\quad + \text{Max} \sum_{i=1}^{n} u_i \sum_{j \in T} y^*_j + \text{Max} \sum_{i=1}^{n} u_i \sum_{j \in S} y^*_j \\
&\leq c^i(S) + c^c(S) + c^i(T) + c^c(T)
\end{align*}
\]

Minimal allocated costs

Suppose that there are \( m \) criteria for representing costs. Let \( [x^i, x^j] (i = 1, \ldots, m) \) be the costs of player \( j (j = 1, \ldots, n) \) where \( v (v_i, \ldots, v_n) \) is the virtual weights for costs. player \( j \) wishes to minimize his costs then we have:

\[
\begin{align*}
&\text{Min} \sum_{i=1}^{n} v_i x^i \\
&s 1 \sum_{i=1}^{n} v_i \sum_{j=1}^{n} x^i_j = 1 \\
&\sum_{i=1}^{n} y^i_j x^i_j \geq 0 \quad (j = 1, \ldots, n) \\
&v_i \geq 0 \quad \forall i \\
\end{align*}
\]

Minimizing \( \sum_{i=1}^{n} v_i x^i 
\]

\[
\begin{align*}
&\text{Min} \sum_{i=1}^{n} v_i x^i \\
&s 1 \sum_{i=1}^{n} v_i \sum_{j=1}^{n} x^i_j = 1 \\
&\sum_{i=1}^{n} y^i_j x^i_j \geq 0 \quad (j = 1, \ldots, n) \\
&v_i \geq 0 \quad \forall i \\
\end{align*}
\]

The weights of costs are nonnegative. A characteristic function of the coalition \( S \) is defined by the linear program below

\[
\begin{align*}
d(S) = \text{Min} \sum_{i=1}^{n} v_i \sum_{j \in S} x^i_j \\
&s 1 \sum_{i=1}^{n} v_i \sum_{j=1}^{n} x^i_j = 1 \\
&\sum_{i=1}^{n} v_i x^i_j \geq 0 \quad (j = 1, \ldots, n) \\
v_i \geq 0 \quad \forall i
\end{align*}
\]

\[
d(S) = \text{Min} \sum_{i=1}^{n} v_i \sum_{j \in S} x^i_j \\
s 1 \sum_{i=1}^{n} v_i \sum_{j=1}^{n} x^i_j = 1 \\
\sum_{i=1}^{n} v_i x^i_j \geq 0 \quad (j = 1, \ldots, n) \\
v_i \geq 0 \quad \forall i
\end{align*}
\]

In the program (22), (23) the costs of all players are nonnegative. Minimal allocated costs game, satisfies a super-additive property.

Theorem 9

The maximal allocated cost game \((N, c)\) and min game \((N, d)\) are dual games, for any \( S \subset N \), we have \( d(S) + d^*(S) + c^i(N \setminus S) + c^c(N \setminus S) = 1 \).

Proof

\[
c^i(N \setminus S) + c^c(N \setminus S) = \\
= \text{Max} \sum_{i=1}^{n} u_i \left( \sum_{j \in S} y^i_j - \sum_{j \in T} y^i_j \right) + \\
= \text{Max} \sum_{i=1}^{n} u_i \left( \sum_{j \in T} y^*_j - \sum_{j \in S} y^*_j \right) + \\
= \text{Max} \left( \sum_{i=1}^{n} u_i \left( \sum_{j \in S} y^i_j - \sum_{j \in T} y^i_j \right) + \\
= \text{Max} \left( \sum_{i=1}^{n} u_i \left( \sum_{j \in T} y^*_j - \sum_{j \in S} y^*_j \right) + \\
= \text{Max} \left( \sum_{i=1}^{n} u_i \left( \sum_{j \in S} y^i_j - \sum_{j \in T} y^i_j \right) + \\
= \text{Max} \left( \sum_{i=1}^{n} u_i \left( \sum_{j \in T} y^*_j - \sum_{j \in S} y^*_j \right) + \\
= 1 - \text{Max} \sum_{i=1}^{n} u_i \left( \sum_{j \in S} y^i_j - \sum_{j \in T} y^i_j \right) + \\
= 1 - \text{Max} \sum_{i=1}^{n} u_i \left( \sum_{j \in T} y^*_j - \sum_{j \in S} y^*_j \right) + \\
= 1 - d(S) - d^*(S) \].
\]

Avoiding occurrence of zero weights and setting preference on weights

In previous sections, we presented a scheme for determining the weights through the program (18), (19), (22) and (23). Some weight may happen to be zero for all optimal solutions. This means that the corresponding criterion is not accounted for in the solution of the game at all. Let us suppose that all players agree to put preference on certain criteria. The zero weight issue can thus be solved in this way (Allen et al., 1997). If all players
agree to incorporate preference regarding criteria, we can apply the following “assurance region method”. For example, we set constraints on the ratio \( w_i, w_j \) respectively. These bounds must be set by agreement among all players. The program (5) is now modified as:

\[
c(S) = \text{Max } \sum w_i x^1(s)
\]

\[
s.t. \quad \sum w_i = 1
\]

\[
L_i \leq \frac{w_i}{w_j} \leq U_i \quad (i = 2, \ldots, m)
\]

\[
w_i \geq 0 \quad \forall i
\]

(27)

Similarly, we can avoid occurrence of zero weight in linear programs of maximal allocated benefits and minimal allocated costs. Then, we have:

\[
c^1(S) = \text{Max } \sum u_i \sum y_j
\]

\[
s.t. \quad \sum u_i y_j = 1
\]

\[
\sum u_i y_j \geq 0 \quad (i = 1, \ldots, n)
\]

\[
L_i \leq \frac{u_i}{u_j} \leq U_i \quad (i = 2, \ldots, s)
\]

\[
u_i \geq 0 \quad \forall i
\]

(28)

\[
d^1(S) = \text{Min } \sum v_i \sum x^1_j
\]

\[
s.t. \quad \sum v_i x^1_j = 1
\]

\[
\sum v_i x^1_j \geq 0 \quad (i = 1, \ldots, n)
\]

\[
v_i \geq \frac{v_1}{v_j} \leq U_i \quad (i = 2, \ldots, m)
\]

\[
v_i \geq 0 \quad \forall i
\]

(30)

The (22), (23) are modified in (27), (28) respectively.

The best coalition

In program (18), (19),(22) and (23) we presented a scheme for computing maximal allocated benefits, minimal allocated cost for coalitions. Also we can compute maximal allocated benefits and minimal allocated costs for members of coalition, using programs (16),(17),(20) and (21). These values can determine the players expected percentages of the total benefit, cost in the game. Each player can increase benefit allocation and decrease cost allocation, establishing coalition. In other words the possible ultimate benefit allocated to the coalition can increase and minimal cost allocated can decrease once the best circumstance is provided. There is a question, how can player \( j \) establish coalition? Now, knowing this it’s easy for the player to examine which other players, she/he can establish coalition with so that he can reach the ultimate benefit ratio and minimal cost ratio. Each player can establish coalition in different ways, chance coalition, coalition concerning players of minimal allocated benefit (cost), coalition concerning players of maximal allocated benefit (cost), coalition with the player enjoying the ultimate benefit and the players with the minimal allocated benefit (cost), coalition with the player enjoying the minimal benefit (cost) and the players with maximal allocated benefit (cost). Clearly, coalition with the player having the ultimate allocated benefit would be better than the others. Coalition with the player having the minimal allocated benefit would be poorer in comparison to others. Now, it’s easy to understand that a player with the minimal benefit ratio establish a coalition with the player who has allocated the ultimate benefit for him/herself and player with the maximal benefit ratio establish a coalition with the player who has allocated the minimal benefit for him/herself. Having established the coalition the player cost ratio would be less or unchanged. Clearly, player with the minimal cost ratio establish a coalition with the player who has allocated the minimal cost for him/herself, and player with the maximal cost establish a coalition with the player who has allocated the minimal cost for himself. These results represented by the example below.
Table 1. Cost and benefit criteria for first of interval.

**NUMERICAL RESULTS**

There are 10 players in this game. Each player uses 2 cost criteria and 4 benefit criteria for first of interval (Table1). We compute maximal allocated benefit and the minimal allocated cost for each player for first of interval. Table 2 show this results (we set constraints in the ratio $u_1$). Similarly, we can compute maximal allocated benefit and minimal allocated cost for end of interval. We now apply this approach to the data in Table 2. 7th player has the minimal allocated benefit and the 10th has the maximal allocated benefit. Also, the 1st has maximal allocated cost and 4th and 9th have the minimal allocated cost.

Consider in Table 3 (A) , $S_1$ is chance coalition , $S_2$ is coalition concerning players of minimal allocated benefit, $S_3$ is coalition concerning players of maximal allocated benefit, $S_4$ is coalition with the player enjoying the minimal benefit and the players with minimal allocated benefit and in Table 3 (B) , $S_5$ is chance coalition $S_7$ is coalition concerning players of maximal allocated cost, $S_8$ is concerning players of maximal allocated, $S_9$ is coalition with the players enjoying the minimal cost and the players with maximal allocated cost and $S_{10}$ is coalition with the player enjoying the maximal cost and the players with minimal allocated cost.

Table 4 shows, establish the coalition the player benefit ratio are increased or unchanged. Also, establish the coalition the player cost ratio are decreased or unchanged. 7th player with the least benefit ratio has the most benefit in $S_4$.10th player with the maximal benefit ratio has the most benefit in $S_5$.4th player with the most cost ratio has the least cost in $S_{10}$.1st player with the minimal cost ratio has the least cost in $S_7$.

**Conclusion**

In this paper, we have studied the common weight issues that connect the game solution with arbitrary weight selection behavior of the players. Regarding this subject, we have proposed a method for compute maximal allocated benefit and minimal allocated costs for interval data. We have introduced coalitions and the ways for finding the best coalitions. In this sense, avoided occurrence zero weight by assurance region method.
