Antibiotics are the most successful form of therapeutics developed for the treatment of disease caused by bacteria. The study aimed to assess the prevalence of *Escherichia coli* and multidrug resistant pattern from environmental sources in Port Harcourt, Rivers State, Nigeria. Forty samples were collected from environmental sources including poultry litter, soil, waste water and cloaca. All samples were inoculated onto prepared Eosin Methylene blue plates and incubated for 24 h at 37°C. Colonies were sub cultured onto sterile nutrient agar plates. Pure isolates were identified using standard microbiological methods. Antibiotic susceptibility was carried out on identified *E. coli*. The study showed that from the samples poultry had 15 (37.5%) *E. coli*, soil 11 (27.5%), waste water 9 (22.5%) and cloaca 5 (12.5%) *E. coli*. However, the highest number of *E. coli* was observed in poultry source and least in cloaca. The results also revealed that the number of *E. coli* from poultry were 7 (46.7%), 5 (33.3%), 2 (13.3%) and 1 (6.7%), soil 6 (54.5%), 1 (9.1%), 3 (27.3%) and 1 (9.1%), waste water 2 (22.2%), 2 (22.2%), 2 (22.2%) and 1 (11.1%) and cloaca 2 (40.0%) and 3 (60.0%), respectively. *E. coli* were susceptible and resistant to classes of antibiotic including Cefazidime, Cefuroxime, Gentamicin, Cefxime, Ofloxacin, Augmentin, Nitrofurantoin and Ciprofloxacin. Hence, the study amongst others that to prevent further emergence and spread of resistant strains in *E. coli*, rational use of antibiotics and regular monitoring of antimicrobial resistance patterns are essential and mandatory.

**Key words:** Antiobiogram, *Escherichia coli*, environment, multidrug, resistance.

**INTRODUCTION**

*Escherichia coli* are Gram negative pathogen with a global distribution rate. It can be isolated from environmental, clinical, and animal sources. Certain strains of *E. coli* cause most clinical and environmental...
mediated diseases. Antibiotic resistance has become a worldwide concern due to the emergence of antibiotic-resistant bacteria which limits the clinical use of antibiotics. Antibiotic resistance increases the prevalence of resistant bacteria in both clinical and environmental sources thus rendering available antibiotics ineffective for therapeutic purposes (Ajuga et al., 2021; Odonkor and Kenned, 2018; Agbagwa and Jirigwa, 2015). Sommer et al. (2017) reported that antibiotic-resistant genes responsible for resistance to a wide variety of antibiotics have been identified in a large range of environments including drinking water, waste water, soil and cloaca, etc., in both developed and developing countries. The main risk for public health is that resistance genes are transferred from environmental bacteria to human pathogens. The potential of the environment to transport microbial pathogens to a greater number of people, causing subsequent illness, is well documented in countries at all levels of economic development. Furthermore, the availability of safe environment is an indispensable feature for preventing epidemic disease and improving the quality of life. Hence, the World Health Organization reported that 80% of all diseases are attributed to unsafe environment. This is to say that developing countries in particular, are plagued with water-related diseases such as diarrhoea which account for 10% of the disease burden in such countries (Ellis and Schoenberger, 2017). Availability of safe environment is a key factor underpinning public health and development of any nation. Environmental sources that may harbour microorganisms include surface water such as lakes, streams, rivers, ponds and underground water such as springs, wells, borehole, soil and animals houses (Oluyege et al., 2009). Lyimo et al. (2016) reported that 748 million, mostly poor and marginalized people, animals, and in the environment, are capable of causing disease, leading to increased morbidity, mortality, and healthcare expenditures (WHO, 2014). Hence, the E. coli found in people and animals is considered a potential reservoir for AMR genes and these genetic traits can be transferred to or to other bacteria found in people, animals, and in the environment (Katakweba et al., 2018). The study intends to assess the prevalence of E. coli and multidrug resistant pattern from environmental sources in Port Harcourt, Rivers State, Nigeria to provide and guide concerted policies for necessary interventions.

MATERIALS AND METHODS

Study area

The research was carried out at the Medical Laboratory of the Department of Microbiology in the University of Port Harcourt which is located at Choba, Rivers State, Nigeria.

Sample collection

Forty samples were collected from environmental sources including poultry, soil, waste water and cloaca. 15 samples were from poultry, soil (11), waste water (9), and cloaca (5). All samples were preserved in cold boxes, transported to the Medical Laboratory of the Department of Microbiology in the University of Port Harcourt within 4 h and maintained at 4°C until use.

Isolation and identification of E. coli

All environmental samples (poultry, soil, waste water soil and cloaca) were inoculated on prepared Eosin Methylen Blue (EMB) agar plates and incubated for 24 h at 37°C. The colonies on the plates were sub cultured onto nutrient agar plates (Oxoid) to obtain pure colony. Pure colonies were stored and subjected to Gram staining selected biochemical test such as: citrate test, indole test, oxidase test, triple sugar iron agar test, methyl red and Voges-Proskuer test for identification (Cheesbrough, 2006). They were further confirmed using E. coli specific 16s rRNA gene fragment of Ec16 primer pairs (F 5'-GACCTCGGGTTAGTTCAAGA-3' and R 5'-CACACGCTGAGCGTGAACCA-3') (Islam et al., 2016). The reaction mixture was prepared by the addition of 3 µl of E. coli DNA, 10 µl PCR master mix, 1 µl of each of the two primers and 6 µl of nuclease free water. The primers have an annealing temperature of 55°C and result in a product with base pair of 588 bp (Islam et al., 2016).

Antibiotic susceptibility testing

Antibiotic susceptibility testing was carried out on identified isolates by the disc diffusion method (CLSI, 2014). In brief, isolates were inoculated on sterile nutrient broth for 18 to 20 h of incubation at 37°C. Inoculum size was adjusted to 0.5 McFarland standards and swabbed onto Muller-Hinton agar. Antibiotic disc was placed and incubated for 24 h at 37°C. The zone of inhibition was measured to the nearest millimetre and all bacterial isolates were classified as sensitive, intermediate, and resistant.

RESULTS

Of the fifty samples collected from various sources, poultry had 15 (37.5%) E. coli samples, soil 11 (27.5%), waste water 9 (22.5%) and cloaca 5 (12.5%) E.coli. However, the highest number of E. coli was observed in poultry source and least in cloaca sample. Detailed result of the overall prevalence of E.coli is presented in Figure 1. Table 1 shows that the number of MDR E. coli from poultry was 7 (46.7%), 5 (33.3%), 2 (13.3%) and 1 (6.7%), soil 6 (54.5%), 1 (9.1%), 3 (27.3%) and 1 (9.1%), waste water 2 (22.2%), 2 (22.2%), 2 (22.2%) and 1 (11.1%) and cloaca 2 (40.0%) and 3 (60.0%), respectively. The identified 40 E. coli were subjected to antibiotic susceptibility testing. Results obtained showed that E. coli from poultry was 47% susceptible, 1% intermediate, and 74% resistant to antibiotic susceptibility test (Figure 2). E. coli from soil (Figure 3) was 33% susceptible, 6% intermediate and 49% resistant to the antibiotic tested. E. coli from waste water (Figure 4) was 28% susceptible, 3% intermediate, and 41% resistant to antibiotic susceptibility test and Figure 5 shows that E. coli from cloaca was 16% susceptible, 1% intermediate, and 23% tested antibiotics.

DISCUSSION

The aim of the study was to assess the prevalence of E. coli and multidrug resistant pattern from environmental sources. The finding of the study showed that E. coli were isolated from poultry, soil, waste water and cloaca. Fifteen numbers of E. coli samples were isolated poultry, soil 11, waste water 9, and cloaca 5. Detailed results are as shown Figure 1 (Overall prevalence of E. coli). Isolates were identified by standard microbiological methods. However, colonial morphology for identification is presented. The results showed that from the samples collected from various sources, poultry had 15 (37.5%) E. coli samples, soil 11 (27.5%), waste water 9 (22.5%) and cloaca 5 (12.5%) E. coli, this shows the presence of multi-drug resistant E. coli in the various samples. The finding of this study confirms that of Galindo-Mendez (2020), Singh et al. (2020) in Indian whose studies reported the prevalence of antibiotic resistant genes among multi-drug resistant E. coli. However, these studies were sampled in human faeces and at least two antibiotic classes were detected. The finding of this study is in conformity with that of Rubab and Oh (2021), Jahantigh et al. (2020) whose studies discovered the
presence of multi-drug resistant in \textit{E. coli}. However, most of these studies were done among STEC isolates and lesions in broiler chickens with gentamicin being the most resistant. By implication, these results indicated that there is high level of the prevalence of multi-drug resistant \textit{E. coli} both in the studied area and other studies as confirmed by Adesoji et al. (2015) and the present study. The present study disagrees with the study carried out by some researchers where the resistant level was higher than the present study. This difference observed could be attributed to the environmental factors, the strain, samples source and other factors (Karami et al., 2006; Xi et al., 2009; Coleman et al., 2012; Chen et al., 2017; Sanganyado and Gwenzi, 2019; Praveenkumarreddy et al., 2020). Multidrug resistant \textit{E. coli} is currently on the increase and more prevalent in developing countries where antibiotic are used indiscriminately in agriculture, veterinary and medicine. Antibiotics are used in agriculture and animals without proper investigation and policies to guide the use of antibiotics. This can be a major avenue for the transfer of antibiotic resistant bacteria to humans via contaminated environmental

Conclusion

This study shows the presence of multi-drug resistant *E. coli* with most showing susceptible and resistance to classes of antibiotic including Ceftazidime, Cefuroxime, Gentamicin, Cefxime, Ofloxacin, Augmentin, Nitrofurantoin and Ciprofloxacin. Hence, to prevent further emergence and spread of MDR resistant *E. coli*, policies guiding the use of antibiotics and regular monitoring of antimicrobial resistance patterns should be put in place to prevent the transfer of resistant bacteria from one source to another.
