Accepted 19 April, 2011

To evaluate the effect of Tai Chi exercise on older people with nephritis, 124 older people with nephritis were asked to practice Tai Chi exercise for 40 min once every day. Results showed that Tai Chi quan exercise significantly decrease high-shear whole blood viscosity, low-shear whole blood viscosity, plasma viscosity, erythrocyte sedimentation rate (ESR), hematocrit (HCT), usea nitrogen, creatinine and creatinine scavenging rate during 12 months of practice. This indicates that Tai Chi exercise is beneficial to prevent and delay nephritis deterioration.

Key words: Tai Chi, nephritis, old people, hematocrit (HCT).

INTRODUCTION

Tai Chi (TC) is a traditional Chinese martial art that has been demonstrated by numerous studies to improve the ability to balance on one leg (Bohannon et al., 1984; Iverson et al., 1990; Schaller, 1996; Hong et al., 2000; Jonsson et al., 2004). The movements engage continuous body and trunk rotation, flexion/extension of the hips and knees, postural alignment, and the coordination of the arms (Swaim, 1999). Five major ancient Tai Chi styles are currently practiced: Chen, Yang, Sun, Wu (Jian Qian), and Wu (He Qin) styles. Each style has a distinctive protocol that differs from the other styles in the postures or forms included, the order in which they appear, the pace at which movements are executed, and the level of difficulty (Yang, 1991).

Nephritis refers to inflammation of one or both kidneys. It can be caused by infection, but is most commonly caused by autoimmune disorders that affect the major organs. For example, those with lupus are at a much higher risk for developing nephritis. In rare cases nephritis can be genetically inherited, though it may not present in childhood (Yang et al., 2000; Nkeh-Chungag et al., 2009).

Nephritis is a serious medical condition which is the ninth highest cause of human death. As the kidneys inflame, they begin to excrete needed protein from the body into the urine stream. This condition is called proteinuria. Loss of necessary protein due to nephritis can result in several life-threatening symptoms. Most dangerous in cases of nephritis is the loss of protein that keeps blood from clotting. This can result in blood clots causing sudden stroke (Dooley and Falk, 2007; Morteza et al., 2010; Lamb et al., 2003).

METHODS

Participants

The participants were recruited from Guangzhou City, China. The sample was composed of 124 older people (73 women and 51 men; mean age of 68.2±6.82 years). The participants were asked to practice Tai Chi quan for 40 min once every day. The study lasted for 12 months. Some biochemical indexes were measured at 3-month intervals. All indexes were measured using an auto-hemorheological analyzer.

Statistics

All data are presented as means ± SE. The results were calculated statistically using 1-way analysis of variance (ANOVA) and the Duncan multiple range test. Differences were considered to be significant at P < 0.05 (Snedecor and Cochran, 1989).

RESULTS AND DISCUSSION

Nephritis is an inflammation of the kidney and is categorized into Glomerulonephritis (inflammation of the glomeruli, when the term ‘nephritis’ is used without further qualification, this is often the condition meant), Interstitial
nephritis (swelling of the area between the renal tubules), Lupus Nephritis (A auto-immune disease factor leading to the inflammation) and Pyelonephritis (swelling due to the spread of a urinary infection to the kidney) (Hodgin et al., 2009). It has been reported by many researchers, that blood rheology plays an important role in the cases of diseases related to the cardiovascular system (Barbenel et al., 1983; Dormandy, 1987; Rezazadeh et al., 2009).

The main factors that affect blood's rheological behaviour, are whole blood viscosity, plasma viscosity, hematocrit, mechanical and physicochemical properties of erythrocytes (Lowe and Barbenel, 1988; Begg and Hearns, 1966; Marinakis, 1994). Significant changes in high-shear whole blood viscosity, low-shear whole blood viscosity, plasma viscosity, erythrocyte sedimentation rate (ESR), and hematocrit (HCT) were observed in the old people (Table 1). “Tai Chi” quan exercise significantly decreases these indexes in practitioners. Moreover, the decrease was strengthen with prolonged practice time. These results indicated that “Tai Chi” exercise could improve urinary disorders induced by nephritis.
