Received 6 January, 2015; Accepted 13 April, 2015

The present study was conducted to investigate the antibacterial effect of *Andrographis paniculata* against selective human pathogens. The plant parts of *A. paniculata* such as leaf, stem and root were studied for its antibacterial activity. Different solvents were used to extract the active components from the plant parts. The antibacterial activity was studied against selective human pathogens viz., *Staphylococcus* sp., *Escherichia coli*, *Salmonella* sp. and *Pseudomonas* sp. Among the different solvents, methanol extract showed greater antibacterial activity against *E. coli* (32.8 mm) followed by *Salmonella Typhi* (24.7 mm), *Pseudomonas* sp. (24.2 mm) and *Staphylococcus* sp. (18.4 mm). So the future investigation was carried out for leaf extract using methanol as solvent to find out the minimum inhibitory concentration for selective human pathogens. The results reveal that 75 µl was optimum for all the test cultures. It shows more activity in *E. coli* (32.3 mm) followed by *S. Typhi* (28.1 mm), *Staphylococcus* sp. (14.1 mm) and *Pseudomonas* sp. (13.4 mm).

Key words: *Andrographis paniculata*, Antibacterial, Andrographolide, minimum inhibitory concentration.

INTRODUCTION

Medicinal plants have grown enormously from the use of herbal products as natural cosmetics and as self-medication by the general public scientific for their beneficial effects (Sharma and Joshi, 2011). In olden ages, antibiotics were produced mostly from the leaves and roots of medicinal plants. The extracts of many plant species have become popular in recent years and attempts have taken to characterize their bioactive principles which gained scope for various pharmaceutical food processing and medical application. *Andrographis paniculata* is an herbaceous plant in the family Acenthaceae, native to India and Sri Lanka. In North-Eastern India the plant is known as Maha-tita literally “King of bitters”, known as various vermicular names (Abhishek et al., 2010). The Tamil has been using Nilavembu-as it is called in Tamil – for centuries.

In Siddha medicine *A. paniculata* used widely to treat fever like cikunguny, swine –flu, typhoid, snake bite and common cold etc. (Dhiman et al., 2012). It is an annual herb. The leaves are used traditionally in Asian traditional medicine and particularly in Ayurveda for treatment of various diseases and illness. The plant is cultivated in many areas, as well. It grows well in a sunny location. The seeds are sown during May and June.

The seedlings are transplanted at a distance of 30 × 60 cm. The seeds are small and remain dormant for 5-6 months. If possible seedlings should be raised in shade to protect them from heat (Seema et al., 2002). It is distributed in tropical Asian countries, often in isolated patches. It can be found in a variety of habitats, such as plains, hillsides, coastlines, roadsides, farms, and wastelands (Prajapati et al., 2003). Approximately, 28 species of are known and indigenous to Asia. The species also found in Hong Kong, Thailand, Brunei, Singapore, and other parts of Asia, where it may or may not be native. It is widely cultivated in southern and South Eastern Asia to treat infections and some diseases. A. paniculata grows erect to a height of 30 - 110 cm in moist, shady places. The slender stem is dark green. The lance-shaped leaves have hairless blades measuring 8 cm long by 2.5 wide. The small flowers are borne in spreading racemes. The fruit is a capsule around 2 cm long and a few millimeters wide. It contains many yellow-brown seeds.

A. paniculata is also used for other medical purpose; for example, digestive problems, blood cleanser, fever, sore throat (Sharma and Joshi, 2011). A. paniculata is used to cure fever and cold (Koul and Kapil, 1994). It is one of the best anti-malarial agent compared to the commercial product of quinine (Parvataneni et al., 2010). The herb has shown an ability to reduce inflammation (heat) and fight viral infections and is used as a principal ingredient in traditional Chinese medicinal formulas for lung support from colds (Sheeja et al., 2006). A. paniculata is a blood purifier, so it is used to cure turbid liver, jaundice, dermatological diseases, dyspepsia, febrifuge and anhelhemic. A. paniculata acts to dispel heat and remove toxin. Andrographaloid was found to be more potent and a standard hepato protective agent (Visen et al., 1993). The whole plant of A. paniculata is used extensively as an anti-inflammatory and antipyretic drug for the treatment of laryngitis, diarrhoea. The juice of fresh leaves generally contains andrographolide. It is used as a domestic remedy in the treatment of colic pain, loss of appetite, irregular stools and diarrhoea (Mishra et al., 2007). Since ancient times, A. paniculata has been known in traditional Asian medicine as an immune system booster, to treat infections in the gastrointestinal tract and upper respiratory tract, harps, sore throat and a variety of other chronic infectious diseases (Wangboonskul et al., 2006). Nowadays microbes are resistance to various antibiotics. The resistant of microbes is due to indiscriminate utilization of commercial antimicrobial medicines supported by many scientists investigation for modern antimicrobial substances from several medicinal plants (Alagesaaboppathi and Kalaiselvi, 2012). Most of the researchers concentrate on screening and minimum inhibitory concentration (MIC) of extracts of plants rather than identifying compounds with activity. In this attempt, we isolated active constituents of the plant and screened for antimicrobial activity which can be used further in research to develop antimicrobial compounds with the isolated compounds or their synthetic analogues reported by Mohamed et al. (2013). The present investigation was carried out to study the antibacterial potential of extract of A. paniculata against selective human pathogens.

**MATERIALS AND METHODS**

**Collection of plant material**

The whole plant of A. paniculata was collected from the trial plots at campus of Faculty of Agriculture, and verified by Dr. Manivannan Professor and Head, Department of Horticulture Annamalai University, Annamalai Nagar, Chidambaram, Tamil Nadu. Fresh and healthy leaf, stem, and root were used to extract bioactive fractions of A. paniculata. The parts of plants which were used for the extract were washed with water to remove soil and dust particles. Then they were dried under shaded place. Dried materials were blended to form a fine powder and store in airtight bottles (Mneenusarma and Sumanjothi, 2011).

**Test organisms**

The human pathogens viz., Staphylococcus sp., E. coli, S. Typhi and Pseudomonas sp., were collected from Jayasekaran hospital, Nagarcoil, Tamil Nadu, India. The test culture was maintained in Nutrient agar slant at 4°C for further studies.

**Preparation of plant extract**

The shade dried coarse powder of the leaf stem and root of A. paniculata were extracted using 250 ml solvent of ethanol, acetone, methanol and water with the help of soxhlet apparatus. The extracts were auto-calved to determine the stability of the crude extracts at the temperature of 121°C for 15 min and then the extracts were stored at 4°C for further use (Daniyan and Mohammed, 2008).

**Assay of antibacterial activity using the agar well diffusion method**

An agar-well diffusion method was employed for determination of antibacterial activities. The freeze-dried extract samples of spices and herbs were dissolved in phosphate buffered saline (PSB, pH 7.0 to 7.2) to the final concentration of 100 mg/ml and sterilized by filtration through 0.22 µm sterilized Millipore express filter. All bacteria were suspended in sterile water and diluted to 10⁶ CFU/ml. The suspension (100 µl) was spread onto the surface of NA medium. Agar wells (4.6 mm in diameter) were cut from the agar with a sterile borer and 60 µl extract solutions were delivered into them. The inoculated plates were incubated at 37°C for 24 h. Antibacterial activity was evaluated by measuring the diameter of inhibition zone of the tested bacteria.

**RESULT**

The antibacterial activity of different plant parts of A. paniculata viz., root, stem and leaf were investigated
Typhi, the activity of stem extract by acetone showed resistance against human pathogens. Methanol showed maximum zone of inhibition (29.2 mm) for S. Typhi sp. Then the activity of root extract of methanol was best. So, further, the solvent of water showed maximum zone of inhibition (11.9 mm) for Salmonella typhi and E. coli the minimum zone of inhibition (8.9 mm) for Staphylococcus sp.

The activity of stem extract of ethanol showed maximum zone of inhibition (23.3 mm) for S. Typhi, and minimum zone of inhibition (8.7 mm) for Staphylococcus sp. The activity of stem extract of methanol showed maximum zone of inhibition (29.2 mm) for E. coli and the minimum zone of inhibition (16.6 mm) for Staphylococcus sp., the antibacterial activity of stem extract of water showed maximum zone of inhibition (13.3 mm) for S. Typhi, and the minimum zone of inhibition (7.5 mm) for Pseudomonas sp.

The activity of leaf extracts of ethanol showed maximum zone of inhibition (28.1 mm) for Salmonella typhi and the minimum zone of inhibition (9.2 mm) for Staphylococcus sp. Then the activity of leaf extracts of acetone showed maximum zone of inhibition (28.6 mm) for S. Typhi and the minimum zone of inhibition (14.9 mm) for Staphylococcus sp. The activity of leaf extracts of methanol showed maximum zone of inhibition (32.8 mm) for E. coli and the minimum zone of inhibition (18.4 mm) for Staphylococcus sp. The antibacterial activity of leaf extracts of water showed maximum zone of inhibition (11.9 mm) for Salmonella typhi and E. coli the minimum zone of inhibition (8.9 mm) for Staphylococcus sp.

The result reveals that methanol based leaf extract was more effective when compared with other extracts and for all solvent used, methanol was best. So, further, minimum inhibitory concentration was studied for methanol extract of leaves. The different concentrations viz., 0, 25, 50, 75 and 100 µl were taken. Then, the well diffusion method was followed for all the pathogens (Table 2). The result reveals that 75 µl was optimum for all the test cultures and it was found to have more activity for E. coli (32.3 mm) followed by S. Typhi, (28.1 mm), Staphylococcus sp., (13.1 mm) and Pseudomonas sp., (14.1 mm). Figure 2 depicts the minimum inhibitory concentration of methanolic leaf extract of A. paniculata against E. coli.

**DISCUSSION**

Infectious diseases are a major cause of morbidity and mortality worldwide. Currently, the ongoing battle against bacteria prevails certainty of evolving, resistance. On the

*Table 1. Antibacterial activity of *Andrographis paniculata* active against selective human pathogens.*

The antibacterial activity of *Andrographis paniculata* root and leaf extracts against human pathogens and the activity of methanol based leaf extract was more effective when compared with other extracts and for all solvent used, methanol was best. So, further, the solvent of water showed maximum zone of inhibition (11.9 mm) for Salmonella typhi and E. coli the minimum zone of inhibition (8.9 mm) for Staphylococcus sp.

Infectious diseases are a major cause of morbidity and mortality worldwide. Currently, the ongoing battle against bacteria prevails certainty of evolving, resistance. On the
other hand, advancement in medical field results in more patients being in critical and immune suppressed states, thus creating a perpetual need for new antibiotics. As a result, it is the right time to discover new antibiotics (Mahesh and Satish, 2008). A. paniculata has a several water soluble lactone andrographoloidic properties. Medicinal plants are more important in field of pharmaceutical industries for new drug preparation (Sule et al., 2010).

Maximum zone of inhibition was recorded with 75 µl methanol extract against S. aureus, in accordance with the previous studies reporting that 75 µl methanol is better than other solvent for antibacterial activity (Pushpendra Kumar Mishra et al., 2013). Therefore, only the 75 µl of methanol extract of A. paniculata leaves were used for further experiments. The present study mainly focused on assaying the efficiency of different plant parts viz., root, stem and leaf of Andrographis paniculata using various solvent extraction procedures against the selected human pathogens.

In the preliminary screening of antibacterial activity of methanol leaf extract of Andrographis paniculata exhibited maximum activity when compared with other plant parts and also from different solvent extracts (Monoharan and Monoharan, 2013). The maximum activity was observed for the pathogens E. coli followed by Salmonella typhi, Staphylococcus sp. and Pseudomonas sp.

The methanolic extracts of Andrographis paniculata at the highest concentration showed the strongest bacterial

inhibitory activity of other extracts. This similar observation reported by many researchers (Negi et al., 2005; Parekh and Chanda, 2010; Al-Bayati, 2008; Kaushik and Goyal, 2011).

The methanol leaf extract was studied for minimal inhibitory concentration concept for various concentrations viz., 0, 25, 50, 75 and 100 µl. Among the different concentrations, 75 µl showed maximum activity for all the pathogenic organisms and recorded highest for E. coli (32.3 mm) and it was on par with 100 µl concentrations. From the result, it was revealed that plant extracts of A. paniculata showed strongest antimicrobial activity for a wide range of pathogens and also more reliable than commercially available antibiotics.

**Conclusion**

A. paniculata has been used in Ayurveda, Unani and Siddha systems of medicine from ancient times. It has wide spectrum of pharmacological activities either in the form of powder, extracts or in its isolated compounds with minimum side effects; several products fortified with extract or isolated compounds have been launched in national and international markets for various diseases. In this context, the present study was carried out to find out the antibacterial potential of various solvent based extract of A. paniculata against selective human pathogens. The antibacterial activity of A. paniculata may be due to the presence of active principle called andrographoloid. In future, the improvements of active principle andrographoloid content in A. paniculata using plant growth promoting rhizobacteria (PGPR) are studied. The enriched A. paniculata plant extracts are further studied for their antibacterial properties against selective human pathogens.
