Pasteurella multocida causes fowl cholera (FC), a contagious bacterial disease of domestic and wild avian species. It is a Gram negative coccobacilli causing acute highly fatal septicemia with high morbidity and mortality rate. Control of fowl cholera is primarily performed by good management practice and vaccination in areas where disease is endemic. For a quality vaccine, high density growth of P. multocida along with its capsule and outer membrane protein (OMP) is necessary. In the present study, physiochemical factors (growth medium, temperature, pH, incubation time and stirring along with aeration affecting growth density) were evaluated. Growth density was determined by colony forming unit (CFU) and dry mass. Physiochemical factors used in maximum growth density (1.32×10¹² CFU or 9 mg/ml) of bacteria were between 35 to 40°C, 7.2 to 8.2 pH and 1000 rpm stirring, along with aeration during incubation of 24 h in Brain Heart infusion (BHI) broth. P. multocida showed maximum growth (1.32×10¹² or 9 mg/ml) in BHI broth with continuous stirring and aeration (1000 rpm) at 38°C for 24 h. Thus, there was a positive co-relation between colony forming unit (CFU) and dry mass of bacteria.

Key words: Brain heart infusion (BHI), aeration, agitation, fermentor, dry mass.

INTRODUCTION

Pasteurella multocida causes fowl cholera (a bacterial disease) in domestic and wild birds (Xiao et al., 2015). The disease is characterized by facial edema, blackening of comb and wattles, diarrhea, dull depressed with high morbidity (up to 50%) and less than 10% mortality in infected flock (Glisson et al., 2003; Choudhury et al., 1985; Kwon and Kang, 2003; Moemen et al., 2012).

Post mortem lesions are enteritis, petechial hemorrhages on the epicardium and serosal membranes, reactive liver and spleen with white to yellow foci (Galnek et al., 1997; Shivachandra et al., 2005; Christensen, 2013). P. multocida can be classified into five different capsular serogroups (A, B, D, E and F) and 16 serotypes. It is further divided into 1: A, 5: A, 9: A serotypes (Rimler and Rhoades, 1989; Benkirane and De Alwis, 2002; Glisson et al., 2008; Mohamed et al., 2012). It is a fastidious organism which grows on enrichment medium such as Brain Heart Infusion Broth (BHI), CSY broth, tryptic soya broth and serum broth.

Usually, CSY broth is commonly used in the
development of vaccine and diagnostics (Sarwar et al., 2013). The causative agent is Gram negative, cocco-
 bacilli, capsular, non-motile and non-hemolytic on blood agar (De-Alwis, 1999; Boyce et al., 2000; Pedersen et al.,
 2003; Tabatabaei et al., 2007). It does not grow on MacConkey agar, but show pure growth on media
 containing potassium cyanide.

Different factors such as culture media, temperature, pH and aeration continuous stirring have effect in in vitro
 growth of bacteria (Imtiaz, 2001; Shah et al., 2008; Sarwar et al., 2013). Limited number of doses has been
 produced due to insufficient growth of bacteria in still culture, using conventional method of vaccine production.
 Therefore, this study is designed to investigate the physiochemical factors which enhance growth density of
 P. multocida in semi controlled bio fermentor.

MATERIALS AND METHODS

Activation of P. multocida

5 mL fresh growth of capsular serotype P. multocida (obtained from Ottoman Pharma 10-km Raiwind Road, Lahore) was transferred
 aseptically in 50 mL of BHI broth (Oxoid). The inoculated material was incubated at 37°C for 24 h and the activated broth culture was
 used for further study.

Factors augmenting immunogen/growth

Culture media such as casein sucrose yeast (CSY)- (Oxoid), tryptic
 soya (TS)- (Oxoid), (BHI) and nutrient broth (NB)- (Oxoid) were
 prepared according to the instruction of the manufacturer. 50 mL of
 CSY, TS and NB broths were transferred to conical flat bottomed
 flask (Pyrex) while 50 mL of BHI broth was transferred to each of
 the fifteen flasks. Each of the flasks was cotton plugged and
 autoclaved at 121°C for 15 min. The flasks containing BHI, CSY,
 TS and NB broth were inoculated aseptically with 5 mL freshly
 growth culture.

The flasks were incubated at 37°C with aeration for 24 h. Each of
 the five flasks containing 50 mL of sterile BHI culture broth was
 incubated at 35, 37, 38, 40 and 42°C with aeration for 24 h. The pH
 of each of the six flasks containing BHI culture broth was adjusted
 to 4, 5.2, 6, 7.2, 8 and 9.2 using 4N hydrochloric acid (Sigma) or 4N
 sodium hydroxide (Sigma). Also, each of the broth was incubated at
 37°C with aeration for 24 h.

Each of the four flasks (A, B, C and D) containing BHI culture
 broth, incubated at 37°C for 24 h was aerated at 500, 750 and 1000
 rpm, respectively with stirring during whole period of incubation. The flask D was incubated without aeration and stirring (still
 culture).

Measurement of growth density

Total viable count in each of the above experiment was determined
 by Pour plate method (Van Soestbergen and Lee, 1969) with some
 modifications and dry mass was determined according to the
 methodology described by Bratbak and Dundas (1984).

RESULTS AND DISCUSSION

Physiochemical factors such as growth media, temperature, pH and agitation affected the growth
 potential of P. multocida. Each parameter has critical significance in augmenting the biomass production in vitro (Sawar et al., 2013). BHI broth showed significantly
 (P<0.05) higher growth of the organism than that
 observed with TS broth, CSY broth and nutrient broth
 (Figure 1, Table 1). Sucrose at rate 0.1 to 2.0% in culture

Figure 2. Effect of temperature on growth of *P. multocida*.

Medium enhances the biomass of *P. multocida* (Shah et al., 2008) with blood and BHI agar routinely used for the isolation of *P. multocida* (Melody et al., 1994). BHI broth is considered as enrichment medium used for the cultivation of *P. multocida* strains, mammalian and avian origin (Melody et al., 1994).

At temperature range 35 to 40°C, *P. multocida* showed maximum growth in BHI broth (Table 2, Figure 2). However, growth was undetectable when bacteria were incubated at temperature above 40°C. Optimum growth of *P. multocida* was detected when incubated at 35 ± 5°C while no growth was recorded at 25 ± 5°C or above 50°C (Imtiaz, 2001; Shah et al., 2008; Sarwar et al., 2013). At pH range 7.0 to 7.8, the organism showed optimum growth (Table 3, Figure 3). Also, at pH below 3 or above 10, organism shows undetectable growth (Imtiaz, 2001; Shah et al., 2008) which indicated that, the pH of BHI broth is critical in biomass production of *P. multocida*.

Note: Different letters in the same column show significant difference (P>0.05).

Aeration influenced the growth of P. multocida. Maximum growth of the bacteria was observed when the solution was agitated at 500 to 550 rpm and growth was declined at higher agitation rate (Table 4, Figure 4). P. multocida showed optimum growth when broth is agitated at 50 to 500 rpm (Imtiaz, 2001; Shah et al., 2008). In Ali et al. (2000), when the broth was provided with enrichment media and fresh filtered air, it resulted in a bacterial culture with \(5 \times 10^{9}\) CFU/mL and 1.68 mg/mL dry weight. Moreover, when incubated in a flask having BHI broth and agitated at 200 rpm, the bacterial culture showed \(10^{9}\) CFU/mL after 3 to 4 h of incubation at 37°C (Tabatabaei et al., 2007). According to Sarwar et al. (2013), dry mass bacterial growth was 8.2 mg/mL measured by centrifugation technique while the bacterial count was \(10^{17}\) CFU/mL.

Repeated culture of P. multocida in vitro results in the loss of its capsule. Thus, after every 2nd passage in laboratory medium the bacterial culture, may be injected in susceptible rabbits through intra-muscular route. In this manner, the bacteria regain its capsule and kill the rabbits. Moreover, mice or calves can also be selected for revival of pathogenicity of the bacteria (Muneer et al., 2005). This methodology is used for biomass production of P. multocida aimed at biologics (vaccine/diagnostics) production (Sarwar et al., 2013).

**Conclusion**

From the study, the bacteria showed \(1.32 \times 10^{12}\) CFU/ml of growth in brain heart infusion broth (pH 7.2), when incubated at 37°C for 24 h in the presence of aeration and stirring.

**CONFLICT OF INTERESTS**

The authors have not declared any conflict of interests.

*Aquarium pump was used to aerate the culture during incubation time. In one experiment the speed was adjusted to 1000 rpm, in second it was 750 rpm and third it was 500 rpm. Each experiment was repeated four times. At the end of incubation time the Colony forming unit (CFU) of *P. multocida* was measured.

ACKNOWLEDGEMENT

The authors are highly grateful to Mr. Usman Farooq Khalid the owner of Ottoman Pharma (Immuno Division), for providing financial support and providing access to laboratory facility in executing the research.
