Accepted 12 June 2013

The preparation and isolation of complexes trans 1,2 diaminocyclohexane N, N, N', N'- tetraacetato cobalt (III) [Co(CDTA)] - and ethylenediamine-tetraacetato cobaltate (III) [Co(EDTA)]- by direct oxidation of cobalt (II) with peroxodisulfate ion in the presence of Ag⁺ ion as a catalyst is being reported. The stoichiometry of the complexes has been confirmed through spectroscopic techniques i.e. UV-Visible, Infrared and Atomic Absorption Spectroscopy. The complexes were found to have similar analytical values, further to confirm the procedure the complex of Co (III) EDTA was first prepared, isolated and analyzed to confirm the structural formula, Co (CDTA)- was also studied as comparatively. The approach was set to characterize compounds as expected to have the molecular formula, K[Co(CDTA)] - xH₂O in crystal form and [Co(CDTA)]- in ionic form.

Key words: Isolated complexes, redox reactions, infrared (IR) spectroscopy, peroxodisulfate protonation.

INTRODUCTION

The nature and the number of bonding sites in multidentate ligands is one of the most interesting and important aspect of present day coordination chemistry. Woodruff et al. (1973) have worked on the structures of metal-EDTA complexes in the solid state and have tried to produce some answers but they could not render to the structures of the metal complexes in aqueous solution. The problem has been carefully considered by Chisholm and Clark (1973) and concluded that the substantial number of EDTA complexes of bivalent metals contained quinque-dentate ligand that is, could be represented by MEDTA[H₂O]²⁻ with one uncoordinated carboxylate group. Jolley et al. (1992) studies support for this idea comes from the observation of a common pK value for these complexes which is related to protonation of the free carboxylate group rather than involving any breakage of a metal-carboxylate bond. Offsetting this

argument is the study of Nobuyuki and Hirosin (1965), which confirmed that definite spectral changes accompany the protonation of the copper(II) and cobalt(II) complexes and this is more easily rationalized in terms of at least some six coordinated EDTA compound.

Micheal and Robert (1992) studied the interaction of multidentate cobalt (II)-chelate complexes with ferricyanide ion. According to them, a cyanide-bridge that is, intermediate bridge is formed between CoCyDTA²⁻ and Fe(CN)₆³⁻ in a manner exactly analogous to that for the CoEDTA²⁻ - Fe(CN)₆³⁻ reaction. CyDTA was chosen because the stereochemistry of the cyclohexyl ring plays an important part in reactions of complex of this ligand as reported by Sivaswaroop et al. (1991). Number of inner-sphere reactions involving cyano bridging have been reported by Loussouarn et al. (1992). In such kind of reactions, when at least one of the product ions is

substitutional labile, the decomposition (or dissociation) of the successor binuclear complex is rapid and conclusion concerning the structure and reactivity of that species must be drawn from indirect evidence as reported by Suzuko et al. (1991).

The self exchange of Co (II) and Co (III) EDTA complexes was first studied by Adamson and Vorres (1956) at pH 2.0 using a 60°C tracer. Schneider and Sheldrick (2002) described an experiment for the light induced electron transferred reaction between $[\text{Co}(\text{EDTA})]^{2-}$ and $\text{S}_2\text{O}_8^{2-}$ by employing $[\text{Ru}(\text{bpy})_3]^{2+}$ as a photocatalyst, but this reaction hardly proceed in the absence of $[\text{Ru}(\text{bpy})_3]^{2+}$. Number of other studies have been undertaken related to complex reaction of EDTA and CDTA complexing agents (Wilkins and Yelin, 1967; Nishida and Kimura, 1987; Albert and Wilkinson, 1970; Ohashi and Yamamoto, 1977; Nakamoto, 1978; Marr and Rockett, 1972; Fornaro and Coichev, 1999; Turlyan and Kohen, 1995; Horacio and Coichev, 2006). Present study reveals the structure of cobalt (III) complexes and their ratios verification through different spectral techniques.

MATERIALS AND METHODS

Chemicals

Cobalt sulfate, Potassium Peroxodisulfate, Silver Nitrate, Ethylenediamine tetraacetic acid -EDTA, Trans-1,2-Diaminocyclohexane-CDTA N,N,N',N'-tetraacetic acid, Sodium Chloride, Ethyl Alcohol, Cobalt(II) Chloride. All the chemicals were of the analytical grade.

Apparatus and instrumentation

Spectrophotometric techniques were used for the element detection in complex. All types of glass wares, flask, beaker, pipette, cylinder etc used were made up of Pyrex and good quality from SCHOTT DURAN. Iron Magnet heater was of IKAMAG_RTC. Double distilled deionized water and oven having CSW-300 system was used. Balance (Analytical Balance) was of mettler HIOT. Shimadzu UV-Visible Spectrophotometer (type 160 A) was used for determination of cobalt (III). Atomic absorption Spectrometer (model Shimadzu) was used for the determination of elements present in the organic part of complex, that is, carbon, hydrogen, nitrogen and oxygen.

Preparation of reagents

Solutions preparation was done in deionized water. The reagent cobalt (II) sulfate, peroxydisulfate, silver nitrate and ligands (that is, CDTA or EDTA) were mixed in solid form and then dissolved in deionized water to get a clear colored solution by help of magnet stirrer and a little heat. Standard solution of cobalt for atomic absorption spectroscopy measurement, of cobalt (II) having 1000 ppm concentration was prepared by dissolving an appropriate amount of cobalt (II) chloride in measuring flask with deionized water and making up to the mark. Three standard solutions pertaining to concentrations of 1, 2, and 3 ppm were prepared from stock solution cobalt (II) chloride. To establish a concentration of cobalt solution to 400 ppm, calculated amount of compound was

dissolved and made up to the mark with deionized water to prepare the solution of concentration beyond 3.5 ppm. The stock solution was diluted to 200 times.

Methodology

0.01 moles of cobalt (II) sulfate, 0.012 moles of ligands (that is, CDTA and EDTA), 0.003 moles silver nitrate and 0.05 moles of potassium peroxodisulfate were dissolved in accurately measured 80 ml of deionized distilled water at room temperature. The dissolution was facilitated using some heat with stirring to get a clear violet-pink solution. Reaction mixture was kept in water bath between temperatures from 85 to 90°C, while stirring for about two hours such that all peroxodisulfate got decomposed. The color of solution was changed from pink to reddish brown. 0.003 moles of sodium chloride was added to hot solution, to remove silver ion as silver chloride. Then the solution was cooled and filtered and that of total volume of filtrate was about 70 cm³. Ethyl alcohol was added to the filtrate in the same volume and it was kept in controlled temperature for overnight to precipitate out and these precipitate were dried to in oven to crystallization. On the very next day reaction mixture was filtered to isolate the pink precipitate which was washed with excess amount of alcohol, re-crystallization was followed by drying in oven at temperature $\geq 90^\circ\text{C}$.

Analysis

Determination of cobalt

Cobalt (III) complex was examined on Shimadzu 160A UV visible spectrophotometer. The value of λ_{max} was calculated with in two different ranges of 200 to 800 nm and at of 300 to 650 nm to observe the wavelength in which the absorbance is maximum. Different maximum absorbances were observed at 380 and 540 nm. Quantitative determination of cobalt element was analyzed by 2380 Perkin – Elmer Atomic Absorption Spectrophotometer. Hollow cathod lamp of Co⁵⁹ and Air-Acetylene flame (air as oxidant and acetylene as a fuel) were applied and the wavelength was adjusted on 240.7 nm to obtain the maximum absorbance reading for cobalt. Stock solution (containing 1.658 g of complex) was prepared as of unknown solution, three standard solutions of cobalt(II) chloride contain 1, 2 and 3 ppm cobalt were prepared to get linear baseline graph of absorbance vs. concentration as the standard procedure as shown. The observations and the graph are shown in Table 1 and Figure 1 respectively.

Elemental analysis of organic part of the molecule

To characterize the structure of the compound, it was analyzed by infrared spectrophotometer. The previous reports have suggest that the method of Nujol mull sampling method for compound. Instead alkali halide disk, spectra was obtained with KBr pellets.

RESULTS AND DISCUSSION

The preparation and isolation were carried out as described in experimental conditions. The crystal pink chloride compounds were isolated and identified by spectroscopic techniques. Spectrophotometric analysis show two different λ_{max} for cobalt III in the UV visible range at 380 and 540 nm as have shown in the Tables 2 and 3 and Figures 2 to 7. The silver catalyzed, direct

oxidation of cobalt II by peroxodisulfate to prepare $[\text{Co}(\text{III})\text{CDTA}]^-$ complex has been studied. The prepared and isolated complexes are expected to contain cobalt metal and other components as carbon, hydrogen, nitrogen and oxygen. The stoichiometry of the complex has been confirmed through spectroscopic techniques that is, UV-Visible, infrared and atomic absorption spectroscopy. Complex was found to have similar analytical values as reported. To understand more and confirm the procedure the complex of Co (III)-EDTA was first prepared and isolated and analyzed to confirm the structure formula, as shown in Figures 6 and 7.

The $[\text{Co}(\text{CDTA})]^-$ was then studied the same manner as $[\text{Co}(\text{EDTA})]^-$ complex. Elemental analysis for the value of cobalt was estimated to have the same % value as reported before. Accordingly the compound is expected to have the molecular formula, $\text{K}[\text{Co}(\text{CDTA})]-$

$x\text{H}_2\text{O}$ in crystal form and $[\text{Co}(\text{CDTA})]^-$ in ionic form (in solution form). The molecular formula of $\text{K}[\text{Co}(\text{CDTA})]-x\text{H}_2\text{O}$ is supposed to be correct, having one hexadentate ligand bonded to one central Co atom $[\text{CoO}(\text{CH}_2)_4\text{N}(\text{CH}_2\text{COO})_2]^-$. The number of hydrated molecules of water is supposed to be more probably two than one molecule. The presence of three molecules of water in the hydrated molecule is not supported by our results as discussed below.

If $x = 1$ (one molecule of water), the molecular weight of $\text{K}[\text{Co}(\text{CDTA})], \text{H}_2\text{O}$ will be 458.35 g/ mole.

Thus the expected percentage of cobalt content would be 12.86%. If number of water molecules present in the hydrated form of complex is two, $x = 2$, the molecular weight of $\text{K}[\text{Co}(\text{CDTA}), \text{H}_2\text{O}]$ would be 476.38, in which

the expected percentage of cobalt contents are to be 12.37%. In the case of $x = 3$ the molecular weight of $K [Co (CDTA)], 2H_2O$ be 476.38 and the expected percentage of cobalt content would be 11.92% as in Table 4.

In the present study the data pertains to the 12.28% of cobalt present in complex. This leads to believe that a molecular formula with two of hydrated water molecules in the coordination sphere of the complex is correct, and also presence of one K^+ ion in the crystal form of the
