Received 10 August, 2015; Accepted 2 September, 2015

This study was carried out to investigate the hypoglycemic effects of ethanol extract and its chloroform and ethyl acetate fractions of *Rhaphidophora glauca* (Wall.) Schottleaves in normal and glucose induced hyperglycemic mice (*in vivo*). Area under curve (AUC) was also calculated during oral glucose tolerance test (OGTT). Ethanol extract and its fractions of *R. glauca* leaves at 400 and 800 mg/kg doses significantly (P < 0.05-0.001) reduced fasting glucose level in normal mice as compared to standard drug glibenclamide (5 mg/kg). Ethanol extract of *R. glauca* (EERG) at 800 mg/kg dose showed the highest hypoglycemic effect among the extract and fractions and it decreased 25.13% of the blood glucose level after 2 h of administration in normal mice, where glibenclamide decreased to 49.30%. In oral glucose tolerance test, at 400 and 800 mg/kg dose of extract and fractions significantly reduced blood glucose level (P < 0.05) at 30 min, but at 60 and 90 min, blood glucose level reduction is not all properly significant as compared to the control. At 120 min, both doses of extract and fractions significantly (P < 0.01) reduced blood glucose level. Whereas glibenclamide (5 mg/kg) significantly reduced glucose level at every hour after administration. EERG at 800 mg/kg dose showed the highest hypoglycemic effect among the extract and fractions and it decreased to 13.28% of blood glucose level after 2 h of administration in glucose induced mice, where glibenclamide decreased to 41.18%. AUC during OGTT of extract and fractions are at the range of 12.713 to 13.188 h.mmol/L., and 14.573 and 9.835 h.mmol/L for control and glibenclamide, respectively. These findings suggest that the plant may be a potential source for the development of new oral hypoglycemic agent.

**Key words:** *Rhaphidophora glauca*, hypoglycemic activity, area under curve (AUC), ethanol extract, fractions, glucose induced.

INTRODUCTION

Several medicinal plants have been reported to be useful in treating diabetes globally and have been used empirically in antidiabetic and antihyperglycemic cures. Antihyperglycemic activity of the plants is principally due to their ability to reinstate the function of pancreatic tissues by causing an increase in insulin production or
inhibit the intestinal absorption of glucose or to the facilitation of metabolites in insulin reliant processes. More than 400 plant species having hypoglycemic activity have been accessible in literature, though, searching for new antihyperglycemic drugs from natural plants is still striking because they contain substances which make obvious alternative and safe property on diabetes mellitus (Haddad et al., 2012; Patel et al., 2012a, b). Most of the plants contain glycosides, alkaloids, terpenoids, flavonoids, carotenoids, etc., that are habitually implicated as having hypoglycemic effect (Salihu et al., 2015).

Diabetes is a metabolic disorder of sugar, fat and protein, influencing a substantial number of populaces on the planet (Matsumoto et al., 2015). Diabetes mellitus is not a solitary disorder, rather it is a gathering of metabolic disorder described by ceaseless hyperglycemia, coming about because of deformities in insulin discharge, insulin activity, or both. Expanded thirst increased urinary yield, ketonemia and ketonuriaare, the basic side effects of diabetes mellitus which occur due to the abnormalities in carbohydrate, fat, and protein metabolism. At the point when ketones body is available in the blood and urine, it is called ketoacidosis; hence, legitimate treatment ought to be taken quickly, else it can prompts other diabetic complications (Low et al., 2015). Diabetes mellitus has brought about critical grimness and mortality because of microvascular (retinopathy, neuropathy, and nephropathy) and macrovascular (heart assault, stroke and fringe vascular sickness) complexities (Singh et al., 2015).

Diabetes is basically ascribed to the fast ascent in undesirable way of life, urbanization and maturing. Hyperglycemia which is the primary side effect of diabetes mellitus produces reactive oxygen species (ROS) which cause lipid peroxidation and layer harm. ROS assumes an imperative part in the improvement of auxiliary complications in diabetes mellitus such as cataract, neuropathy and nephropathy. Antioxidants protect β-cells from oxidation by inhibiting the peroxidation chain reaction and along these lines they assume an important part in the diabetes. Plants containing regular cancer prevention agents, for example, tannins, flavonoids, vitamin C and E can safeguard β-cell work and anticipate diabetes prompted ROS development. Polyphenols, which are ordered into numerous gatherings, for example, flavonoids, tannins and stilbenes, have been known as health-beneficial properties, which incorporate free radical searching, restraint of hydrolytic and oxidative proteins, antiinflammatory activity and hypoglycemic potentiality (Patel et al., 2011; Roy et al., 2015). Aldose reductase as a key catalyst, catalyze the diminishment of glucose to sorbitol and is related in the perpetual complications of diabetes, such as peripheral neuropathy and retinopathy. Utilization of aldose reductase inhibitors and α-glucosidase inhibitors has been reported for the treatment of diabetic complications (Jung et al., 2011).

Oral hypoglycemic medications can bring about different adverse reactions, including hypoglycemia, weight gain, fluid retention, cardiac failure, and gastrointestinal side effects (El-Refaei et al., 2014; Chiniwala and Jabbour, 2011; Kar et al., 2015). Specifically, hypoglycemia is connected with cardiovascular incidents and cognitive dysfunction, and it is known that hypoglycemic episodes can lead to falls and cracks (Geier et al., 2014). Elderly patients are more inclined to create hypoglycemia than more youthful patients when treated with different medications, and in addition quickly after release from healing center, if they have renal failure, and if their diet is poor and they are also less likely to detect the onset of hypoglycemia (Kamei et al., 2015; Penfornis et al., 2015). These distinctions make treatment of diabetes more troublesome in elderly patients, so that cautious training and drug selection are needed.

period of 10 days under shade and then powdered with a mechanical grinder, passing through sieve #40, and stored in a tight container. The powdered of leaves (900 g) of *R. glauca* was soaked in 1.3 L ethanol for 7 days with occasional shaking and stirring and filtered through a cotton plug followed by Whatman filter paper number-1. The extract was then concentrated by using a rotary evaporator at reduced temperature and pressure. A portion (50 g) of the concentrated ethanol extract (EERG) was fractioned by the modified Kupchan partitioning method (Islam et al., 2010; Bulbul et al., 2011) into chloroform (CHFRG, 13 g) and ethyl acetate (EAFRG, 12 g).

Chemicals and reagents

All the chemicals and reagents were of analytical grade. Ethanol, chloroform and ethyl acetate were purchased from Merck, Germany. Normal saline solution was purchased from Beximco Infusion Ltd. Rapid View™ (Blood glucose monitoring system, Model: BIO-M1, BIO USA Inc, California, USA) with strips were purchased from Andorkilla, Chittagong. Glucose was purchased from local scientific market, Chowkbazar, Chittagong. Glibenclamide was obtained from Square Pharmaceutical Ltd., Bangladesh.

Animals and experimental set-up

Swiss albino mice, weighing about 28 to 35 g, were collected from Jahangir Nagar University, Savar, Bangladesh. The animals were furnished with standard lab nourishment and refined water ad libitum and maintained at natural regular day-night cycle having proper ventilation in the room. All the experiments were conducted in an isolated and noiseless condition. Then, the study protocol was approved by the P&D Committee, Department of Pharmacy, International Islamic University Chittagong, Bangladesh. The animals were acclimatized to laboratory condition for 7 days prior to experimentation.

Acute toxicity study

For acute toxicity study, forty Swiss albino female mice were used. According to the method of Walum (1998), mice were divided into four groups of five animals each. Different doses (1000, 2000, 3000 and 4000 mg/kg) of ethanol extract and its chloroform and ethyl acetate fraction of *R. glauca* leaves were administered by stomach tube. Then, the animals were observed for general toxicity signs.

Experimental protocol for in vivo hypoglycemic activity

**Hypoglycemic effect in normal mice**

Mice were kept fasting overnight with free access to water. Group I was treated as control group. Group II was treated with glibenclamide (5 mg/kg body weight), Groups III to VIII were treated with ethanol extract and its chloroform and ethyl acetate fraction of *R. glauca* leaves at 400 and 800 mg/kg body weight, respectively. Before administration of the drug, extract and fractions solutions fasting blood glucose levels were estimated by glucose oxidase method (Barham and Trinder, 1972). Then blood glucose levels were again estimated after 2 h of administration of drug and extract solutions. Glucose levels were measured by Rapid View™ (Blood glucose monitoring system, Model: BIO-M1, BIO USA Inc, California, USA). The maximum hypoglycemic effect of glibenclamide was found after 2 h of its administration. Percent decrease of blood glucose level after 2 h was measured using the following equation:

\[
\text{Decrease} (\%) = \frac{GL_{before} - GL_{after}}{GL_{before}} \times 100
\]

Where, \(GL_{before}\) = Blood glucose level before drug or extract and fractions administration, \(GL_{after}\) = Blood glucose level after drug or extract and fractions administration.

**Hypoglycemic effect in glucose induced hyperglycemic mice (OGTT)**

Oral glucose tolerance test (OGTT) was performed according to the standard method (Xia et al., 2013) with minor modification. Group I was treated as normal control group. Group II was treated with glibenclamide (5 mg/kg body weight). Groups III to VIII were treated with ethanol extract and its chloroform and ethyl acetate fraction of *R. glauca* leaves at 400 and 800 mg/kg body weight, respectively. Glucose solution (1 g/kg body weight) was administered at first. Then, drug and extract solutions were administered to the glucose fed. Serum glucose level of blood sample from tail vein was estimated using glucometer at 0, 30, 60, 90 and 120 min. Areas under the curves (AUC) for OGTT were calculated to evaluate glucose tolerance (Purves, 1992). Percent decrease of blood glucose level after 120 min was measured using the following equation:

\[
\text{Decrease} (\%) = \frac{GL_{0\text{ min}} - GL_{120\text{ min}}}{GL_{0\text{ min}}} \times 100
\]

Where, \(GL_{0\text{ min}}\) = Blood glucose level at 0 min, \(GL_{120\text{ min}}\) = Blood glucose level at 120 min.

Statistical analysis

The results were expressed as the mean±standard error of mean (SEM). The results were statistically analyzed using repeated measures analysis of variance with Dunnett’s and Bonferroni multiple comparison when compared with control in OGTT. Paired t test was performed to show significant variation between before and after blood glucose level. P<0.05, P<0.01 and P<0.001 were considered as statistically significant. Statistical programs were used GRAPHPAD PRISM® (version 6.00; GraphPad Software Inc., San Diego, CA, USA).

**RESULTS**

Acute toxicity study

None of the animals showed behavioral, neurological or physical changes characterized by symptoms such as reduced motor activity, restlessness, convulsions, coma, diarrhea and lacrimation at the limit dose of 4000 mg/kg of ethanol extract and its chloroform and ethyl acetate fraction of *R. glauca* during the observation period. In addition, no mortality was observed at the test dose. Thus, the median lethal dose (LD₅₀) of the plant extracts was found to be greater than 4000 mg/kg.

Values are presented in mean±SEM (<i>n</i>=5). EERG: Ethanol extract of *R. glauca*; CHFRG: Chloroform fraction of ethanol fraction; EAFRG: Ethyl acetate fraction of ethanol extract. (A) Values in same row with different superscripts are significantly different for <i>P</i>&gt;0.05, <i>P</i>&lt;0.01 and <i>P</i>&lt;0.001. Paired t-test was performed to analyze before and after relationship. (B) Values with different superscripts in same column are significantly different from control after the administration of standard and different doses of the extract and fractions for <i>P</i>&gt;0.05, <i>P</i>&lt;0.01 and <i>P</i>&lt;0.001. One-way ANOVA followed by Dunnett’s multiple comparison was performed to analyze this comparison. (C) Values with different superscripts (<i>x, y, z</i>) are significantly different from each other in the same column among standard and different doses of the extracts after administration. One-way ANOVA followed by Bonferroni multiple comparison was performed to analyze this inter relationship.

Hypoglycemic effect in normal mice

Both doses of ethanol extract, fractions and glibenclamide significantly reduced fasting blood glucose level. Glibenclamide showed significant reduction at level of <i>P</i>&lt;0.01. Dose of 400 and 800 mg/kg leaves ethanol extract of *R. glauca* and its fractions showed significant reduction at the level of <i>P</i>&lt;0.05 and <i>P</i>&lt;0.001, respectively. These results suggest that hypoglycemic activity of 800 mg/kg dose and glibenclamide has similar significant level. All results are presented in Table 1 and percentage of decrease of blood glucose level in normal mice after 2 h with different treatment are shown in Figure 1. EERG at the highest dose of 800 mg/kg decreased blood glucose level (25.13%) than other treatments (accept standard Glibenclamide).

Hypoglycemic effect in glucose induced hyperglycemic mice (OGTT)

Investigational induction of hyperglycemia resulted in increased glucose level in blood (comparing the result of control of 0 and 1 h) (Table 2). Both dose of leaves...

Values are presented in mean±SEM (n=5). EERG: Ethanol extract of *R. glauca*; CHFRG: Chloroform fraction of ethanol fraction; EAFRG: Ethyl acetate fraction of ethanol extract. (A) Values with different superscripts in same column are significantly different from control at each specific hour after the administration of standard and different doses of the extract and fractions for *P*>0.05, *P*<0.01 and *P*<0.001. One-way ANOVA followed by Dunnett’s multiple comparison was performed to analyze this comparison. (B) Values with different superscripts (a, b, γ) are significantly different from each other in the same column among standard and different doses of the extract, fractions and standard. Bonferroni multiple comparison was performed.

Figure 2. Percentage decrease of blood glucose level after treatment with drug, extract and fractions in glucose induced mice.

extract and its fractions did not manifest any significant reduction in 30 min after administration. Most significant reduction (P<0.05) was observed for 800 mg/kg dose of ethanol extract of *R. glauca* and its fractions at 120 min. At 120 min, this dose also showed significant reduction (P<0.05). Standard glibenclamide (5 mg/kg) showed significant reduction in 30, 60, 90 and 120 min. These findings suggest that evidently 800 mg/kg dose is more potent than 400 mg/kg dose. Time interaction with each specific hour in this experiment was also found significant (P<0.05 and 0.001). All results are presented in Table 2 and results of AUC of OGTT are also presented in Table 2. Percentage of decrease of blood glucose level in glucose induced mice after 2 h with different treatment are shown in Figure 2. EERG at the highest dose of 800 mg/kg decreased blood glucose level (13.28%) than...
other treatments (accept standard Glibenclamide).

DISCUSSION

In this study, ethanol extract and its chloroform and ethyl acetate fractions of leaves of R. glauca exerted significant hypoglycemic activity in both fasting glucose level reduction in normal mice and oral glucose tolerance test in glucose induced hyperglycemic mice. Decrease of blood glucose level after 2 h of treatment is very well significant when compared with the control.

There are numerous pharmaceutical items which are accessible in current medicinal treatment have a long history of utilization as home grown cures, including ibuprofen, opium, digitalis and quinine. An expansive number of world’s populace who live in creating nations cannot take the advantages of the present day pharmaceuticals as those are extremely expensive. More or less 25% of modern drugs used in the United States have been derived from plant origins (WHO, 2008). So, research on phytomedicine has got great momentum in recent years to find out noble pharmaceuticals.

Diabetes is a metabolic disease connected with host of difficulties, for example, intense and endless inconveniences. The intense intricacies may be activated by metabolic disorders including ketoacidosis and non-ketotic coma and infections, but these indications can be moderately very much controlled. Then again, the endless entanglements have a tendency to exacerbate as the diabetes advances. Chronic complications associated with diabetes include macroangiopathies, such as coronary artery disease and cerebrovascular disease, and microangiopathies, such as neuropathy, orthostatic hypotension, retinopathy and nephropathy (Chang et al., 2006; Takayuki et al., 2006; Gogoi et al., 2014; Toma et al., 2015).

In the normal mice, ethanol extract and all fractions reduced fasting blood glucose level in normal mice after the treatment. EERG at 800 mg/kg dose decrease 25.13% glucose level among extract and fractions, where standard drug glibenclamide decreased 49.30%. This is evident that this extract did not supply glucose in the blood due to its administration.

The OGTT is generally considered as more susceptible for the screening of impaired glycaemia, because it detects changes in post-prandial glycaemia that tend to precede changes in fasting glucose. All the current diagnostic criteria for diabetes depend on a threshold value imposed on a continuous distribution of blood glucose levels. Yet, the correct glycemcic threshold that discriminates ‘normal’ from diabetic is not obvious. Though screening for undiagnosed type 2 diabetes remains a contentious issue, there is clear evidence that once it is diagnosed, complications can be prevented in many patients (Vamos et al., 2012; Hemmingsen et al., 2015). OGTT measures the body's ability to use glucose, the body’s main source of energy. OGTT can be used to diagnose pre diabetes and diabetes. The ethanol extract and its fractions of leaves of R. glauca showed significant ability to reduce the elevated glucose level in normal mice as compared to the standard drug glibenclamide, where EERG showed the highest hypoglycemic activity in both examined model.

The OGTT determines the shape of the glucose curve based on the measurements at 0, 30, 60, 90 and 120 min. From the glucose curve, AUC was determined using Trapezoidal Rule. AUC during OGTT for screening hypoglycemic effect of extract and fractions are at the range of 12.713 to 13.188 h.mmol/L, and 14.573 and 9.835 h.mmol/L for control and glibenclamide, respectively.

These outcomes suggest that ethanol extract and its chloroform and ethyl acetate fractions of R. glauca leaves possess a hypoglycemic principle and can be useful for the treatment of diabetes. Further studies are warranted to isolate the active principle and to find out its accurate mechanism of action.

Conclusions

From the study, it was concluded that R. glauca may have hypoglycemic effect, but not sure about how this extracts and fractions can exert potent hypoglycemic activity. It is a logical inference that this plant may recover the metabolism of glucose and increase insulin secretion by stimulating beta cells. It is possible to propose that the bioactive compounds present in the leaves extract and its fractions may be responsible for versatile effects. Based on the literature search, this is the first study about hypoglycemic activity of R. glauca. That is why the exact mode of action is not determined yet. However, further co-ordinate and well-structured studies would be required to isolate the bioactive compounds and determine their underlying molecular mechanism of action on diabetes induced mice model. These findings suggest that the plant may be a potential source for the development of new oral hypoglycemic agent.

Conflict of Interests

The authors have not declared any conflict of interests.

ACKNOWLEDGEMENTS

The authors are grateful to the authority of International Islamic University Chittagong, Bangladesh, for providing the facilities to conduct this research work. The authors are thankful to the Taxonomist and Professor, Dr. Shaikh Bokhtear Uddin, Department of Botany, University of Chittagong, for identifying the plant. The authors like to
thank Mr. Md. Mominur Rahman, Assistant professor, IIUC for supervision of the experiment. The authors are also thankful to all members of GUSTO (A research group), for their kind help in the experiment.
