Received 19 June, 2012; Accepted 2 July, 2014

This study conducted at the campus of Abomey-Calavi in December 2009 evaluated students conceptions in relation to the theme of human immunodeficiency virus/acquired immune deficiency syndrome (HIV/AIDS). A target population of students was approached through a questionnaire. This descriptive study showed that 45% of the students were not satisfied with the level of fighting against AIDS in Calavi campus. 81.81% of the students have already completed at least once time their HIV test. However, only 33% of them are aware of the figures of the real situation of HIV-AIDS in the student environment. 42.43% of the students were already sexually active and only 42% of them make systematic use of condoms with their partners. 48.48% of the studied population doubt the effective protection offered by condoms with HIV/AIDS, but 93.93% of them are aware of the actual existence of evil in the student environment. 60.60% of the target studies were between 20 and 25 years old. Nearly 90% of the students want the intensification of sensitization sessions in Calavi campus. This study provides an overview on knowledge about HIV/AIDS by students and could help to develop better strategies to fight the pandemic of the century among students. The student world is an important link in the fight against HIV/AIDS and greater attention should be paid to this layer.

Key words: Students, human immunodeficiency virus/acquired immune deficiency syndrome (HIV/AIDS), infection, condoms, test, Calavi campus.

INTRODUCTION

The sixth axis of the Millennium Development Goals (MDGs) known as "Stop the spread of human immunodeficiency virus/acquired immune deficiency syndrome (HIV/AIDS) by the year 2015" is dedicated to HIV infection, because of the size it takes and especially its socioeconomic impact (Primary Neurosurgical Life Support [PNLS], 2009). The future of humanity is dependent on the ability of men to fight effectively against the scourge of HIV/AIDS (Unité Focale de Lutte contre les IST/VIH/Sida, 2006). AIDS pandemic is now a concern of all humanity, because firstly, the extent of the damage it causes in terms of health and secondly, its negative impact on nations development. Despite efforts by the international community to curb the pandemic, infection
It is no exaggeration to say that HIV/AIDS is a tragedy of modern times whose dimensions devastating in sub-Saharan Africa have significantly altered the socio-economic parameters. This undermines efforts for decades, but also currently (Pisani, 2000; Schoof, 1999; UNAIDS, 2001). If epidemic obviously affects the growth of developing countries and increases poverty, its impact on education systems is even more devastating and far-reaching long-term (Le Monde, 2002). In Benin, the situation is no less alarming. Indeed, since the first case of HIV/AIDS in 1985, we got to 8,196 cumulative cases of people living with HIV (PLHIV) in December 2005. Benin is a country in West Africa with about eight million people. As shown in Figure 1, the seroprevalence is relatively low, estimated between 1 and 1.3% for the whole country (United Nations Programme on HIV and AIDS [UNAIDS], 2010). Since 2006, HIV epidemic is stationary with a prevalence in Benin, which hovers around 1.8% with no significant difference between years (Figure 2). The epidemic is concentrated on specific groups called risk groups. The seroprevalence of HIV infection was 0.1% among pupils and students who are 2.1% of reported groups. The seroprevalence of HIV infection was 0.1%.

It is important to add to this free screenings organized by the national program of fighting against AIDS (Benin) in December 2005. Questionnaires, a camera, ballpoint pens were used in this study. This is a descriptive study that took place during an awareness session at Abomey-Calavi campus. Among the participants who were present, only thirty-three students have fully responded to the questionnaire. These thirty-three students aged from 20 to 25 years were invited to participate in data collection. Nine questions were administered to each student, after informed consent. The selected people were free to participate or not in the survey. After counting and coding, the questionnaires were numbered and archived. The data were entered into Epi-Data. A clearance program has corrected the inconsistencies and entry errors. Data were analyzed using Statistical Package for Social Sciences (SPSS) version 17.0.

RESULTS AND DISCUSSION

Student satisfaction about the fight against AIDS

Forty five percent of the study population is not satisfied. 55% of the students nonetheless feel that the struggle among students is good. Although more than half of those resources delivered a good mark at the fight, it remains true that 45% still have a contrary view. Indeed, nearly half of young the people questioned said that the fight among students should be reviewed. This could be due to the fact that the Abomey-Calavi campus has many associations fighting against the pandemic but unfortunately, this diversity in the student struggle that the funding is not coordinated. Thus, adverse effects were noted and nothing is done while everyone wants something to be done. Moreover, most of these organizations are much more interested in financial interests than the fight against the scourge, so they are not sustainable in general.

Completion of testing by students

On the implementation of the screening test, 81.81% of students have already done this test at least once in their life. This is probably due to free availability of this test in all the country's public courses. Moreover, the promiscuity of health centers and various audio-visual messages have certainly had a positive impact on the choice of these students to do their testing for HIV/AIDS. It is important to add to this free screenings organized by the national program of fighting against AIDS (Benin) in Calavi campus.

Pandemic's numbers knowledge by students

Thirty three percent of the students surveyed are aware
of the figures of the real situation of HIV-AIDS in the student environment. Indeed, very few students know the infection rate of young students by the AIDS virus, while many studies were conducted by the national program fighting against AIDS of Benin in 2008, 2009, 2010, 2011, and 2012. This situation shows that the release of the results of these studies should be stronger among the students. Integration of the theme of HIV/AIDS in education programs at the university would probably correct this situation. These results are confirmed by the work of Karfo et al. (2010) which showed that the limited knowledge of the students on sexual risk behavior was related to the fact that AIDS is not sufficiently taken into account in programs of secondary and higher education in Burkina Faso.

**Sexual activity among students**

Forty two percent of students had at least one time sex intercourse. These results were in contrast with those of Karfo et al. (2010) who noticed that 72.80% of Burkinabe students said they had sex intercourse at least one time. They believed that Burkinabe students have a high sexual freedom. The significant difference between these data could be explained by the difference between the two studies. In fact, the study of Karfo et al. (2010) is more recent. Nevertheless, it should be noted that Benin students are more very young (60.60% of the target study were between 20 and 25 years) and the study conditions often harsh impact on their sexual frenzy. Only four in ten use condoms consistently before sex. Karfo et al. (2010)
also found that nearly 34% of the Burkinabe students have had unprotected sex during their study. A U.S. study also found that few students used condoms. The argument most often mentioned is that the condom dulls the sexual experience for both man and his partner (Thrippeswamy and Gorvine, 2012). In Benin, many young people still continue to associate the use of condoms to "eat the banana with its skin." This shows that despite all the advice of the scientific community, condom use has still not taxed in the child layer. The limitation of sexual pleasure, the feeling of "eat banana skin" is a serious obstacle to this mode of protection, the condom.

48.48% of students doubt the protection offered by condoms and HIV/AIDS, and this fully justifies the fact that they do not use them systematically. Many of students believe that condoms sometimes contain the AIDS virus and that is the cause of viral contamination. These unscientific designs show that serious efforts are still required to the awareness of young students.

**Notions of students in relation to HIV/AIDS**

Ninety three percent of the students are aware of the existence of effective HIV/AIDS in the student environment, despite the many risks they often adopt. Strunin (1991) noticed that African and American students were less knowledgeable than their white colleagues about the risks of HIV/AIDS, while being much more sexually active. This situation exposes them to more risks of disease transmission. Sikand et al. (1996), in a study on 771 students from New York, stressed that students have a fairly good knowledge of HIV/AIDS in general, but tend to engage in risky behaviors, despite what they know. This poses the problem of awareness. Would it not be preferable to mass sensitize individual approaches to targets, emphasizing the consequences associated with their actions? Trying to touch their conscience individually would certainly give better results.

Nearly 90% of the students want the intensification of sensitization sessions in Calavi campus which should no longer be done only during the world day of fighting against AIDS. It largely confirms the need of strategic actions for students in the Abomey-Calavi campus.

**Conclusion**

This study provides an overview in terms of knowledge about HIV/AIDS by students and could help to develop better strategies to fight the pandemic of the century among students. It is not an epidemiological study strictly but this was done to lead some decisions. University is a rich environment in pressure from all sides and a restructuring of the fight against the pandemic would be desirable. This is then an appeal to donors and strategic partners at various levels so that together the target zero can be made a reality.

**ACKNOWLEDGEMENT**

The authors are very grateful to the Project
NUFFIC/NPT/151 at the Polytechnic School of Abomey-Calavi for all the dynamism in the fight against HIV/AIDS among students.
