Received 8 May, 2019; Accepted 29 July, 2019.

Limited treated options to Salmonellosis exist due to the emergence of extended spectrum beta lactamases (ESBLs). This study determined the prevalence of common ESBL genes (*bla*<sub>SHV</sub>, *bla*<sub>CTX-M</sub>, *bla*<sub>OXA</sub>) and profiled their antimicrobial resistance drug pattern. A descriptive cross-sectional study that involved 16 *Salmonella enterica* isolates from diarrhoeic children at the University of Calabar Teaching Hospital and 39 isolates from healthy birds in poultry farms within the Calabar metropolis. Standard disc diffusion method determined antimicrobial susceptibility while Polymerase Chain Reaction (PCR) using specific primers identified the beta-lactamase genes. All 55 isolates phenotypically demonstrated ESBL production. All 55 salmonella isolates were resistant to Cefotaxime and Nalixidic acid. All the clinical isolates were susceptible Ciprofloxacin and Norflaxacin. The poultry isolates however exhibited varied degrees of resistance to Ciprofloxacin and Norflaxacin. All 55 *Salmonella* isolates carried the *bla*<sub>SHV</sub> genes, *bla*<sub>CTX-M</sub> gene (94.5%) *bla*<sub>OXA</sub> gene (18.2%). Molecular characterization identified the *bla*<sub>SHV</sub> gene as the most prominent. This study provides relevant data that would help in the implementation of policies regarding the use of antimicrobial agents in clinical and veterinary settings as well provide antimicrobial treatment guidelines that would strengthen infection control processes.

Key words: Salmonella enterica, Antimicrobial-resistance, ESBL-genes, Poultry-sources.

INTRODUCTION

*Salmonella enterica* serovars remains one of the major causes of food borne gastroenteritis. Non-typhoid salmonellosis usually causes diarrhoea that may not necessarily require antimicrobial therapy (Andino and Hanning, 2015; Cohen Stuart et al., 2012; Nadimpalli et al., 2019). Nonetheless, in cases where the non-typhoid infection becomes invasive, severe complications may result hence requiring antimicrobial treatment options (Cohen Stuart et al., 2012). The emergence and spread of antibiotics resistance especially with the detection of extended spectrum beta lactamases (ESBLs) in *Salmonella enterica* serovars has however limited...
treatment options because of their acquired resistance to most beta-lactam antibiotics and fluoroquinolones which would have been sufficient first line treatment for both mild and severe salmonellosis (Al-Naemi et al., 2008; Ifeanyi et al., 2015).

Studies have shown ESBL production by Salmonella enterica to be plasmid mediated and readily transmitted amongst members of the Enterobacteriaceae family as a result (Rotimi et al., 2008). This potential exacerbates the spread of antimicrobial resistance amongst the other members of the Enterobacteriaceae family against beta-lactam antibiotics and other commonly used antibiotics (Oghenevo et al., 2016). Studies have also shown that ESBLs occur because of mutations in the \( bla_{TEM-1}, \) \( bla_{TEM-2} \) or \( bla_{SHV-1} \) genes, which are commonly found in the Enterobacteriaceae family. Others enzymes, notably from the cefotaxime resistance family (CTX-M), represent plasmid acquisition of broad-spectrum beta-lactamases originally determined by chromosomal genes (Bajpai et al., 2017). These mutations gave rise to the alterations in their amino acid configuration and conferred on these enzymes the ability to hydrolyze a broader spectrum of antibiotics (Bajpai et al., 2017).

More than 350 different naturally occurring ESBL variants have been discovered and classified into nine distinct structural and evolutionary families based on their amino acid sequence comparisons (Sharma et al., 2010). They include, \( bla_{TEM}, \) \( bla_{SHV}, \) \( bla_{CTX-M}, \) \( bla_{PER}, \) \( bla_{VER}, \) \( bla_{GES}, \) \( bla_{BES}, \) \( bla_{TLA} \) and \( bla_{OXA} \) (Sharma et al., 2010).

Not much data have been documented regarding the prevalence of the ESBL-producing genes responsible for the antimicrobial drug resistance, especially in Nigeria. This study determined the prevalence of the common ESBL genes (\( bla_{SHV}, \) \( bla_{CTX-M}, \) \( bla_{OXA} \)) in Calabar state, Nigeria and profiled their antimicrobial resistance drug pattern.

MATERIALS AND METHODS

Study area

This study was carried out within the Calabar Metropolis in Cross River state, Nigeria. Calabar is the capital city of Cross River State in the South-South geopolitical zone of Nigeria. Cross River State shares boundaries with Benue State to the North, Ebonyi and Abia States to the west and to the east by the Republic of Cameroon. The city is administratively divided into Calabar Municipal and Calabar South Local Government Areas (LGAs). Calabar covers a surface area of about 406 km\(^2\) (157 sq mile) and a population of 371,022 at the 2006 census.

Study design

This was a descriptive cross-sectional study designed to investigate the prevalence of common ESBL (\( bla_{OXA}, \) \( bla_{SHV}, \) \( bla_{CTX-M} \)) genes among Salmonella strains obtained from diarrheic patients in the University of Calabar teaching hospital and local poultry farms within the Calabar metropolis. Study period was between November 2017 and February 2018.

Ethical consideration

The Ethical Committees of the selected hospital approved the protocol for this study. Approval was also obtained from the Cross River State Ministry of Health, conveyed via CRS/MH/CGSE-H/018/Vol/123 and the Health Research Ethical Committee of University of Calabar. Consent was sought from all study participants and guardians of the poultry farms prior to the collection of samples.

Isolation and identification of Salmonella species

Sixteen (16) Salmonella enterica isolates were randomly recovered from the faeces of diarrhoeic children attending the University of Calabar teaching hospital and 39 Salmonella enterica isolates obtained from healthy birds randomly selected in some local poultry farms within the Calabar Metropolis. This gave a total of 55 Salmonella isolates. Each of the isolates was sub-cultured on MacConkey agar prior to confirmation. Each typical Salmonella enterica colony was confirmed by means of the 16s rDNA amplification.

The typical Salmonella colonies were further sub-cultured overnight in 5 ml of Luria Bertani (LB) broth and centrifuged at 14000 rpm for 3 min. The cells were re-suspended in 500 μl of physiological saline and heated by means of a heating block at 95°C for 20 min. The heated bacterial suspensions were then brought to cool on ice and re-centrifuged at 14000 rpm for 3 min. The supernatant (containing the DNA) was transferred to a 1.5 ml micro-centrifuge tube and stored at -20°C for further analysis. DNA quantification of the extracted genomic DNA was carried out using the NanoDrop 1000 Spectrophotometer.

The DNA of each typical Salmonella isolate was extracted and used for the amplification of the 16s rRNA region of the isolates' DNA using a specific primer set (27F: 5'-AGAGTTTGATCTGGCTCAG-3' and 1492R: 5'-CGTTACCTTGTAGACTT-3'), by means of the ABI 9700 Applied Biosystem thermal cycler at a final volume of 50 microliters for 35 cycles. The Polymerase Chain Reaction (PCR) mix included: X2 Dream Taq Master Mix supplied by Inqaba, South Africa (Taq polymerase, dNTPs, MgCl\(_2\)), the primer sets at a concentration of 0.4 M and the extracted DNA as template. The PCR conditions were as follows: Initial denaturation at 95°C for 5 min, denaturation at 95°C for 30 s, annealing temperature at 52°C for 30 s, extension at 72°C for 30 s for 35 cycles and final extension at 72°C for 5 min. The product was resolved on a 1% agarose gel at 120 V for 20 min and viewed by means of a UV trans-illuminator.

DNA sequence analysis was performed using direct sequencing of both strands by means of the BigDye Terminator kit on a 3510 ABI sequencer (Inqaba Biotechnological, Pretoria - South Africa). The obtained DNA sequences were edited using TraceEdit. Highly similar sequences were downloaded from GenBank in the National Centre for Biotechnology Information (NCBI) using BLASTn (http://www.ncbi.nlm.nih.gov/blast). The Salmonella enterica isolates were confirmed by a 100% match with the 16s rDNA of the downloaded sequences of Salmonella enterica.

Antimicrobial susceptibility testing and detection of ESBL production

This study considered the use of thirteen commercially available antibiotic disc types (LiofilChemDiagnostic, LD) which included; Norfloxacin (NOR-10 μg), Nalidixic acid (NA-30 μg), Cloximoxazole (CLO-50 μg), Amikacin (AK-30 μg), Ciprofloxacin (CIP-5 μg), Imipenem (IMI-10 μg), Chloramphenicol (C-30 μg), Ceftazidime (CAZ-30 μg), Cefotaxime (CTX-30 μg), Cefepime (FEP-30 μg), Aztreonam (ATM-30 μg), ESBL screen disc kit (Cefotaxime, Aztreonam, Norfloxacin, Imipenem, Nalidixic acid, Aztreomycin, Sulfadiazine, Chloramphenicol, Cefotaxime and Ceftriaxone), and Amoxicillin/Clavulanate disk (GLS-25 μg) as per the Clinical and Laboratory Standards Institute (CLSI) guidelines (2019). The Kirby-Bauer disc diffusion technique was used to determine the antibiotic susceptibility. The disk diffusion test was performed on Mueller- Hinton Agar plates. Plates were incubated at 37°C for 18-24 h. The diameter of the zones of inhibition was measured and compared with the interpretive criteria provided in the CLSI guidelines (2019). Antimicrobial resistance was only considered significant when the zone of inhibition was less than the interpretive criteria values.

Identification of ESBL genes

ESBL detection was performed using PCR assay. The primers used were as follows: 27F (5'CGTTACCTTGTAGACTT3') and 1492R (5'CGGTTACCTTGTTACGACTT3'). The PCR conditions used were as follows: Initial denaturation at 95°C for 5 min, denaturation at 95°C for 30 s, annealing temperature at 52°C for 30 s, extension at 72°C for 30 s for 35 cycles and final extension at 72°C for 5 min. The product was resolved on a 1% agarose gel at 120 V for 20 min and viewed by means of a UV trans-illuminator.

DNA sequence analysis was performed using direct sequencing of both strands by means of the BigDye Terminator kit on a 3510 ABI sequencer (Inqaba Biotechnological, Pretoria - South Africa). The obtained DNA sequences were edited using TraceEdit. Highly similar sequences were downloaded from GenBank in the National Centre for Biotechnology Information (NCBI) using BLASTn (http://www.ncbi.nlm.nih.gov/blast). The Salmonella enterica isolates were confirmed by a 100% match with the 16s rDNA of the downloaded sequences of Salmonella enterica.
Cefotaxime+Clavulanic acid, Cefotaxime+Claxacillin and Cefotaxime+Clanlic acid+ Cloxacillin). The susceptibility of the isolates to antimicrobial agents was determined using the Kirby-Bauer disk diffusion method (Cheesbrough, n.d.; Faiilah et al., 2013). A bacterial lawn was prepared by transferring 4 to 5 colonies of the same morphological type in a tube containing 2.5 ml sterile normal saline by means of a sterile inoculating loop. The suspension was vortexed and its turbidity compared with barium chloride (0.5 McFarland Turbidity Standard; 1.0 x 108 CFU/µL). The optical density of the standard was regularly monitored with a spectrophotometer at λ=625 nm and 1 cm light path (ODλ=0.08 - 0.1) (Cheesbrough, n.d.). One hundred micro liters of the inoculum was spread on iso-sensitivity test agar plates. The excess inoculum was siphoned with sterile Pasteur pipettes. Plates were allowed to dry at room temperature in a laminar flow. Disks containing predetermined amounts of antibiotics were then dispensed unto the bacterial lawn using a pair of sterile forceps and gentle pressure applied to ensure complete contact with the agar. The disks were placed 15 mm away from the edge of the plate and 25 mm away from each other. The plates were inverted within 15 minutes after the disks were dispensed and incubated at 37°C for 16 to 18 h. After incubation, they were examined by reading the diameters of the inhibition zones and interpreted in accordance with the description of the United States Clinical and Laboratory Standard Institute (Cheesbrough, n.d.). The isolates showing resistance towards more than three different groups of antimicrobials such as quinolones, aminoglycosides, and cephalosporins, etc., were considered multidrug resistant strains.

The detection of ESBLs producers using the ESBL screen disc kit was performed on the isolates that showed resistance to the third generation cephalosporin antibiotics by disk diffusion method. Briefly, a disc of amoxicillin-clavulanic acid-30 µg was placed on the center of the Muller-Hinton agar plate inoculated with the resistant strain, followed by placing three different cephalosporin discs (cefotaxime-30 µg, ceftriaxone-30 µg and cefazidime-30 µg) around the amoxicillin-clavulanic acid-30 µg, 20 mm each and incubated for 24 h at 37°C.

Examination/interpretation of plates
Enhancement of the inhibition zone, indicating synergy between clavulanic acid and any one of test antibiotics, will be regarded as presumptive for the production of ESBLs. Zone diameters of Ceftriaxone ≤ 26 mm, Cefotaxime ≤ 24 mm and Cefazidime ≤ 28 mm will be considered presumptive for ESBLs production by screening.

Quality control
*Klebsiella pneumoniae* 700603 and *Escherichia coli* 25922 were used as positive and negative control strains respectively for ESBLs production by screening.

Detection of blaCTX-M, blaSHV and blaOXA genes by PCR
The CTX-M gene was amplified using the primer set CTX-M/F: 5'-CGCTTTCGGATGTTGCAG-3' and CTX-M/R: 5'-ACCGGATATCGTGGT-3' on an ABI 9700 Applied Biosystems thermal cycler at a final volume of 25 µl for 35 cycles. The PCR mix included: X2 Dream Taq Master Mix supplied by Inqaba, South Africa (Taq polymerase, DNTPs, MgCl), the primers at a concentration of 0.4 M and the extracted DNA as template. The PCR conditions were as follows: Initial denaturation, 95°C for 5 min; denaturation, 95°C for 30 s; annealing, 52°C for 30 s; extension, 72°C for 30 seconds for 35 cycles and final extension, 72°C for 5 min. The PCR product was resolved on 1% agarose gel at 120V for 20 min and visualized on a UV trans-illuminator.

The SHV gene was amplified using the primer set SHV/F: 5'-CGCTGTGTATTCTCCT-3' and SHV: 5'-CGAGTAGTCACCAGATCCT-3' on an ABI 9700 Applied Biosystem thermal cycler at a final volume of 25 micro liters for 35 cycles. The PCR mix included: X2 Dream Taq Master Mix supplied by Inqaba, South Africa (Taq polymerase, DNTPs, MgCl), the primers at a concentration of 0.4 M and the extracted DNA as template. The PCR conditions were as follows: Initial denaturation, 95°C for 5 min; denaturation, 95°C for 30 s; annealing, 56°C for 30 s extension, 72°C for 30 s for 35 cycles and final extension, 72°C for 5 min. The product was resolved on 1% agarose gel at 120V for 15 min and visualized on a UV trans-illuminator.

The OXA gene was amplified using the primer pair OXA/F: 5'-AGCGTTAAATTAGCCC-3' and OXA/R: 5'-CTTGAATGAAAGGTTGGCG-3' on an ABI 9700 Applied Biosystems thermal cycler at a final volume of 25 micro liters for 35 cycles. The PCR mix included: X2 Dream Taq Master Mix supplied by Inqaba, South Africa (Taq polymerase, DNTPs, MgCl), the primers at a concentration of 0.4 M and the extracted DNA as template. The PCR conditions were as follows: Initial denaturation, 95°C for 5 min; denaturation, 95°C for 30 s; annealing, 55°C for 30 s; extension, 72°C for 30 s for 35 cycles and final extension, 72°C for 5 min. The product was resolved on 1% agarose gel at 120V for 15 min and visualized on a UV trans-illuminator.

Statistical analysis
The data generated in the cause of this study from the antimicrobial susceptibility tests were analyzed using the Statistical Package for Social Sciences (SPSS Inc., Chicago, IL, USA, version 22.0.). P-values of less than 0.05 (< 0.05), was considered of statistical significance.

RESULTS
Table 1 revealed the antimicrobial resistance profile of the *Salmonella enterica* isolates from clinical and poultry sources. All the *Salmonella enterica* isolates (n=55) from both clinical and poultry sources produced ESBL. All the *Salmonella* isolates from the clinical source (n=16) were resistant to Clotrimoxazol. All 55 the *Salmonella enterica* isolates were resistant to Cefotaxime and Ceftriaxone. All the clinical *Salmonella enterica* isolates showed no resistance to Ciprofloxacin and Norfloxacin.

Table 2 showed the distribution of blaSHV, blaOXA and blaCTX-M genes. All 55 *Salmonella enterica* isolates carried the blaSHV gene while blaOXA and blaCTX-M were observed in 18.2%(10) and 94.5%(52) of the isolates, respectively. The proportions of occurrence of the bla genes in both the clinical and the poultry *Salmonella* isolates were not of statistical significance (P>0.05). The blaSHV and blaCTX-M occurred well in predominance over the blaOXA gene in both the clinical and poultry *Salmonella enterica* isolates.

Figure 1 characterized the combination of bla genes possessed by the *Salmonella enterica* isolates from clinical and poultry sources. From the clinical sources, 7 and 9 *S. enterica* isolates carried only blaCTX-M and blaSHV while 4 *S. enterica* isolates carried both the blaCTX-M and blaSHV genes in combination. Also, all three bla genes

Figure 1. Combination of bla genes among the clinical and poultry Salmonella isolates.

under study were carried by 3 clinical Salmonella isolates.
From the poultry isolates, 16 and 17 isolates respectively carried only the bla<sub>CTX-M</sub> and bla<sub>SHV</sub> gene while 15 isolates carried both the bla<sub>CTX-M</sub> and the bla<sub>SHV</sub> gene combination. Also, 7 isolates carried all three bla genes under study in combination.

DISCUSSION

It became imperative to profile antibiotic resistance patterns because incorrect identification of antibiotic resistance usually leads to inappropriate antibiotic prescription, which may in turn select and give rise to new resistant genes. This study profiled antibiotic
resistance and determined the prevalence of the common ESBL-producing genes (bla<sub>SHV</sub>, bla<sub>CTX-M</sub>, bla<sub>OXA</sub>) in Calabar state, Nigeria.

*S. enterica* isolates were extracted from 55 isolates of poultry and clinical sources. Based on the result of the ESBL phenotypic screening test kit carried out in this study, all the *S. enterica* isolates were ESBL producers. All 55 isolates demonstrated 100% resistance to nalidixic acid and 100% susceptible to ciprofloxacin and norfloxacin antibiotics. This agrees with several studies carried out in India where salmonella isolates demonstrated 100% resistance to nalidixic acid with susceptibility to ciprofloxacin (Crump et al., 2003; Kownhar et al., 2007; Ye et al., 2018). These antibiotics belong to the quinolone/fluoroquinolone drug class. Studies have shown Quinolone resistance to be as a result of mutations in the DNA gyrase (*gyrA* and *gyrB*) and topoisomerase IV encoding (*parC* and *parE*) genes (Heisig et al., 1995; Ye et al., 2018). Other studies have also reported the presence of plasmid mediated quinolones resistant (PMQR) genes carried by the ESBL-producing plasmid, which facilitates the selection of higher-level resistance to quinolone drugs (Ahamed Riyaaaz et al., 2018; Carfora et al., 2018; Jacoby et al., 2014; Kongsoi et al., 2015). A combination of both factors with the possible presence of PMQR genes to a greater extent, we believe could be responsible for the observed resistance to Nalidixic acid and the increased resistance to Ciprofloxacin and Norfloxacin in the poultry isolates.

Other studies have also suggested that the in vitro resistance to nalidixic acid could be used as a pointer to the actual level of in vitro resistance to ciprofloxacin (Campioni et al., 2017; Klemm et al., 2018). According to the Clinical and Laboratory Standard Institute (CLSI) guidelines, the resistance to any antimicrobial agent in the fluoroquinolone drug class has an impact on the resistance of other antimicrobial agents within this drug class (Sahu et al., 2018). This implies that the resistance observed by the *Salmonella enterica* to nalidixic acid in this study is a pointer to the development of resistance to other members of the fluoroquinolone class of antimicrobial agents such as ciprofloxacin and norfloxacin in humans in the Calabar region. This is important information given that fluoroquinolones are regarded as the antimicrobial class of first choice for the treatment of severe infections caused by *S. enteica* as well as other pathogenic Enterobacteriaceae in humans.

Results further indicated that fluoroquinolone resistance was higher in poultry isolates in comparison to the clinical isolates. This agrees with several studies carried out in Europe, Asia and North America where resistance to fluoroquinolones by *S. enterica* was far higher in animals than in humans (Britto et al., 2018; Gouvêa et al., 2015; Nelson et al., 2007). Given that poultry is one of the most preferred foods of animal origin, this study suggests that the resistant *S. enterica* isolates in humans could have come from animals via the food chain.

This study showed high rates (93.8 and 59% from clinical and poultry sources respectively) of resistance by the *Salmonella* isolates to chloramphenicol. This finding was in consonance with a similar study carried out in Brazil were the sensitivity of chloramphenicol was found to be as high as 95% among children with salmonellosis (Brown et al., 2018; Ferreira et al., 2011). The high resistance observed suggests the frequent use of chloramphenicol in both the clinical and veterinary setting.

The emergence of ESBL resistance to beta-lactam antibiotics has also introduced a new hurdle in the treatment of salmonellosis as extended-spectrum cephalosporins (beta-lactam antibiotics drug class), which were typically the antibiotics of choice for mild salmonellosis has become insufficient. Results showed an enhanced degree of resistance to the third and fourth generation Cephalosporins (Cefepime, Cefotaxime, Ceftazidime) thus thwarting the reliability of these antibiotics in the treatment of salmonellosis. In judicious use in both humans and poultry, we believe could be the most probable reason for the selective pressure and consequent resistance to these drugs. Therefore, we suggest strict selection and rotation of antimicrobial agents coupled with the continuous monitoring of susceptibility profiles of antimicrobial agents in order to manage the emergence and spread of cephalosporin resistance.

All the salmonella isolates in this study carried the ESBL-producing *bla<sub>SHV</sub>* gene in combination with the *bla<sub>CTX-M</sub>* and *bla<sub>OXA</sub>* genes making *bla<sub>SHV</sub>* the most prominent ESBL-producing gene from *S. enterica* isolates in this study.

Conclusion

Other combinations may exist in Calabar, as this study does not account for other known *bla* genes and recommend that more resources be dedicated to fund further research on this area. Nonetheless, the diversity of the *Salmonella* isolates as a result of the dissemination of these genes is a call for concern and emphasizes a need for an extensive investigation for the presence of these genes in Nigeria as well as the implementation of strict antimicrobial policies in a bid to restrict the spread of these resistance genes and prevent the emergence of new resistant strains.
