Accepted 18 October, 2010

*Myristica andamanica* is grown only in the Andaman and Nicobar Islands in India. In order to evaluate the wound healing activity of *M. andamanica*, five different solvent extracts were prepared from the leaves of the plant. Methanol, ethanol, ethyl acetate, chloroform and hexane were used for the extraction of the active ingredients. Excision wound model on Swiss albino mice was used to assess the wound healing activity of the leaves. Remarkable wound healing activity was observed with the ointment formulation of the methanol extract at 1% concentration. Wound contraction was calculated as percentage of the reduction in wound area. A specimen sample of tissue was isolated from the healed skin of each group of mice for the histopathological examination. The results of histopathological examination also supported the outcome of excision wound models. Hematoxylin & Eosin stained sections and Van Gieson’s stained sections were checked for collagen deposition. Toluidine blue stained sections were checked for metachromatic staining of mast cells. The present study demonstrated that the aerial parts of *M. andamanica* promote wound healing activity in mice as a preclinical study.

Key words: *Myristica andamanica*, phytochemical analysis, excision wound model, wound healing activity, histopathological examination.

INTRODUCTION

Worldwide the herbal industry is picking up at a fast pace. Herbs and botanicals now appear in more products and have more medicinal applications than ever before. India is blessed with diverse agro-climatic conditions and is a major source for a wide variety of medicinal plants. But the production potential is largely underexploited.

When we look back over 250 years ago, people of many continents for the most part resorted to herbal and traditional medicine. Likewise in India too, Ayurveda systems offered botanical medicines and took care of the health of our nation. Almost 25 to 40% of the active components of the synthetic medicine of allopathic medicine had origins from higher flowering plants of the world and the clues to discover them came from folklore medicines of various cultures.

Although the allopathic medicines are extremely effective in handling short term and emergency health conditions, it has been largely ineffective in treating some of the multifactorial chronic diseases. The relative strength of modern system of medicine over the traditional system is in its vast pharmacopoeia, technological advancement in surgical tools or procedures and in handling of acute diseases. Despite the fact that many new medicines are being added in allopathy, only about 30% of the known 2000 diseases are cured, 50% are being treated symptomatically. Approximately, 20% of the allopathic medicines have

considerable side effects.

**Medicinal uses of Myristica andamanica**

*Myristica andamanica* is a species of plant in the *Myristicaceae* family. It is endemic to India. *M. andamanica* is commonly known as Jaiphal in India. This herbal plant is grown only in the Andaman and Nicobar Islands in India. It has been widely used in many Indian recipes and Ayurvedic formulations. It is an aromatic, carminative, hallucinogenic, stimulant that is considered effective in digestive, dehydration and skin disorders like ringworm and eczema. The paste of the herb is prepared by rubbing it on a stone slab in ones’ own early morning saliva before cleansing the mouth and is applied once daily as a specific remedy in the treatment of these conditions. The principal constituent of *M. andamanica* is oil that act as a counter irritant and stimulates blood flow to the area where it is applied.

The powder of *M. andamanica* mixed with fresh amla juice is a valuable remedy for insomnia, irritability and depression. *M. andamanica* mixed with honey is given to infants who cry at night for no apparent reason to induce sleep. The powder of *M. andamanica* mixed with apple juice or banana is used as a specific remedy for diarrhea caused by indigestion of food. The same quantity of nutmeg powder taken with a tablespoon of fresh amla juice thrice daily is effective for indigestion, hiccups and morning sickness. *M. andamanica* has beneficial results in treating dehydration caused by vomiting and diarrhea, particularly in cholera. An infusion prepared from half a nutmeg, in half a liter of water, given with tender coconut water, in doses of 15 grams at a time is an effective treatment. When mixed with a half boiled egg and honey, it makes an excellent sex tonic. It prolongs the duration of the sexual act if taken an hour before intercourse. In case of running nose, a paste made from nutmeg with cow's milk and 75 mg of opium should be applied to the forehead and the nose. It will provide quick relief. *M. andamanica* coarsely powdered and fried in sesame oil, until all the particles become brown is effective as an external application to relieve any rheumatic pain, neuralgia and sciatica.

**MATERIALS AND METHODS**

**Plant material**

The plant material, *M. andamanica* was collected from Andaman and Nicobar islands. The leaves of the plant were shade dried and powdered.

**Preparation of extract**

5 g of aerial part of the powdered sample was submitted to successive solvent extraction separately with 100 ml each of methanol, ethanol, ethyl acetate, chloroform and hexane at room temperature for 24 h. This was repeated three times and 300 ml of the solvent extract was collected for each of the solvent. The solvent extract thus obtained was evaporated at 40°C to dryness in a rotary evaporator in vacuum (Pesin et al., 2009).

**Percentage yield**

The percentage yield was calculated from the product that was obtained after evaporation.

Percentage yield = \( \frac{\text{Weight of the product obtained after evaporation}}{\text{Weight of the powdered sample taken initially}} \times 100 \)

**Preliminary phytochemical investigation**

**Test for saponins**

300 mg of extract was boiled with 5 ml of water for 2 min. The mixture was cooled and mixed vigorously and left for 3 min. The formation of frothing indicates the presence of saponins.

**Test for tannins**

An aliquot of the extract was added to sodium chloride to make 2% strength. It was filtered and mixed with 1% gelatine solution. Precipitation indicates the presence of tannins.

**Test for triterpenes**

300 mg of extract was mixed with 5 ml of chloroform and warmed for 30 min. The chloroform solution is then treated with a small volume of concentrated sulphuric acid and mixed properly. The appearance of red colour indicates the presence of triterpenes.

**Test for alkaloids**

300 mg of extract was digested with 2 ml hydrochloric acid. This acidic filtrate was mixed with amyl alcohol at room temperature and the alcoholic layer was examined for the appearance of pink colour which indicates the presence of alkaloids.

**Test for flavonoids**

The presence of flavonoids was determined using 1% aluminium chloride solution in methanol, concentrated hydrochloric acid, magnesium chloride and potassium hydroxide solution.

**Chromatographic analysis**

The five different solvent extracts obtained were analysed using HPTLC to find out which solvent extract contains the maximum active ingredients. The solvent having maximum number of peaks is the one with maximum active ingredients.

**Gel formulation**

50 g of the powdered sample was submitted to successive solvent extraction with 1000 ml methanol at room temperature for 24 h. This was repeated three times and 300 ml of the solvent extract was

collected. The methanol extract obtained was evaporated at 40°C to dryness in a rotary evaporator in vacuum. The product thus obtained was used for gel formulation. 1 g of the dried solvent extract was made up to 100 g using Vaseline and a paste was made.

Animals

The animal experiments conducted during the present study were approved by the Institutional Animal Ethical Committee (IAEC), SRM University (Ethics Clearance Number: 07/IAEC/09). Male albino Swiss mice weighing 25 to 30 g were used in the wound healing model experiments.

The study was performed according to the international rules considering the animal experiments and biodiversity right. The animals were left for 15 days for acclimatization. They were maintained on standard pellet diet and water throughout the experiment. The mice were divided into three groups of six animals each (n = 6). Six animals were used for the treatment group, six for the positive control group and six for the negative control group. 1% (w/w) *M. andamanica* ointment was applied on the treatment group. 5% (w/w) Povidine Iodine ointment was applied on the positive control group (Kalyon et al., 2009). Plain Vaseline was applied on the negative control group.

Excision wound model

Excision wound models were used to evaluate the wound healing activity. Excision wound model was employed to have information about wound contraction and wound closure time on the three groups of animals. The back hairs of the animals were depilated by shaving.

A wound was created on the dorsal interscapular region of each animal by excising a predetermined area of 7 mm x 7 mm skin under ether anaesthesia (Suguna et al., 1996). Wounds were left open and the medicine was applied topically twice a day (once in the morning and evening) on to each mouse till the wound was completely healed (Tramontina et al., 2002).

Measurement of wound area

The progressive changes in wound area were monitored by a camera every fourth day. The size of the wound was also measured using a scale daily and the wound area was calculated. Wound contraction was calculated as percentage of the reduction in wound area (Werner et al., 1994):

\[
\text{Percentage of wound contraction} = \left( \frac{\text{Initial wound area} - \text{Specific day wound area}}{\text{Initial wound area}} \right) \times 100
\]

Histopathological examination

A specimen sample of the tissue was isolated from the healed skin of each group of mice for the histopathological examination (Sadaf et al., 2006). The cross sectional full thickness skin specimens from each group were collected at the end of the experiment to evaluate the histopathological alterations. Samples were fixed in 10% buffered formalin, processed and blocked with paraffin and then sectioned into 5 µm thick sections. The sections were stained with Hematoxylin and Eosin stain (HE), Van Gieson’s stain (VG) and Toluidine blue stain (TB). Hematoxylin and Eosin stained sections and Van Gieson's stained sections were checked for collagen deposition. Toluidine blue stained sections were checked for metachromatic staining of mast cells (Jagetia and Rajanikant, 2005).

Statistical analysis of the data

The data on the percentage of wound contraction was statistically analysed using one-way analysis of variance (ANOVA) followed by Dunnett’s test. The values of P ≤ 0.001 were considered to be statistically significant. The data on histopathological examination were considered to be non-parametric and so no statistical tests were performed.

RESULTS

Percentage yield

The percentage yield of various extracts of *M. andamanica* was calculated in Table 1. From the percentage yield it was observed that the methanol extract gave the maximum amount of yield and the hexane extract gave the minimum amount of yield.

Preliminary phytochemical analysis

Methanol extract was evaluated for presence of various phytochemical constituents by performing different qualitative chemical tests that are reported. It showed the presence of anthraquinone, glycosides, saponins, tannins and phytosterols (Khandelwal, 2005) in Table 2.

From the phytochemical analysis it was observed that *M. andamanica* preliminarily contains amino acids, carbohydrates, alkaloids, lipids and glycosides. Histopathological observation suggested that the phytochemical content of the methanol extract might be responsible for the collagen formation at the proliferative

**HPTLC analysis**

HPTLC analysis results are given in Figures 1 to 5. From the HPTLC analysis it was observed that the methanol extract contains the maximum amount of phytochemical compounds and the hexane extract contain the minimum amount of phytochemical compounds. Therefore, the methanol extract of *M. andamanica* was used in the treatment of wounds on Swiss albino mice by using excision wound models to verify the claimed traditional use of the plant on a scientific procedure. Moreover, histopathological examination of the animal tissues treated with the extract was also assessed. The specimen slides observed for the treatment group, positive control group and negative control group were analysed.

**Measurement of wound area**

The wound area was measured and calculated on a daily basis. The percentage of wound contraction was monitored everyday from the 0th day till the 12th day. On the 12th day all the six mice under positive control were healed, whereas, in the mice under negative control, the healing is delayed. The healing is intermediate in the case of mice under treatment group.

**Reduction in wound area**

Figure 6 shows reduction in wound area for mice in treatment group compared to mice in positive control group and mice in negative control group. This graph has been calculated for a period of 12 days. The x - axis denotes the number of days and the y - axis denotes the wound area in square millimeter.
Percentage of wound contraction

The figure shows percentage of wound contraction for mice in treatment group compared to mice in positive control group and mice in negative control group. This graph has been calculated for a period of 12 days. The x-axis denotes the number of days and the y-axis denotes the percentage of wound contraction.

The figure shows contraction of wound area on mice in treatment group compared to mice in positive control group and mice in negative control group (Figures 7-9).

Tissue stained with Hematoxylin and Eosin Stain (HE)

Treatment Group: Collagen is seen in pink colour. Muscle is seen in deep pink colour. Basophilic cytoplasm is seen in purple color. Nuclei are seen in blue colour. Positive Control Group: Collagen is seen in pink colour. Muscle is seen in deep pink colour. Basophilic cytoplasm is seen in purple colour. Nuclei are seen in blue colour.
Negative Control Group: No deposition of collagen or muscles are seen which indicates that the tissue has not still developed. Proper nucleus has not still developed since no blue colour is observed.

_Tissue stained with Van Gieson’s Stain (VG)_

**Treatment Group:** Collagen is seen in bright red colour. Cytoplasm, muscle, fibrin and RBC are seen in yellow colour. Nucleus is seen in blue colour. Positive **Control Group:** Collagen is seen in bright red colour. Cytoplasm, muscle, fibrin and RBC are seen in yellow colour. Nucleus is seen in blue colour. **Negative Control Group:** No deposition of collagen is seen.

Figure 7. Percentage of wound contraction.
**Tissue stained with toluidine blue Stain (TB)**

**Treatment Group:** Mast cells are seen in blue colour.

**Positive Control Group:** Mast cells are seen in blue colour.

**Negative Control Group:** No mast cells are observed which indicates that tissue development has not started.

**DISCUSSION**

Wound healing is a complex and dynamic process of restoring cellular structures and tissue layers in damaged tissue as closely as possible to its normal and original state (Clark, 1985). Wound contraction is a process that occurs throughout the healing process, commencing in the fibroblastic stage where the area of the wound undergoes shrinkage (Chitra et al., 2009). Wound healing can be discussed in three phases (Figure 10). They are:

1. Inflammatory phase
2. Proliferative phase
3. Maturational or Remodelling phase

It is dependent upon the type and extent of damage occurred, the general health of the host and the ability of the tissue to undergo repair.

**Inflammatory phase**

The inflammatory phase is characterized by haemostasis and inflammation.

**Proliferative phase**

Inflammatory phase is followed by epithelialisation, angiogenesis and collagen deposition.

**Remodelling phase**

In the maturation phase which is the final phase of wound...

**Figure 9.** Histopathological examination of the healed tissues excised on the 12th day.

**Figure 10.** Hypothetical flowchart of the wound healing mechanism.
healing, the wound undergoes contraction resulting in a smaller amount of apparent scar tissue (Phillips et al., 1991).

Granulation tissue which is formed in the final part of the proliferative phase is primarily made up of fibroblasts, collagen, oedema and new small blood vessels. The increase in dry granulation tissue weight in the test treated animals suggests higher protein content (Devipriya and Shyamaladevi, 1999). The methanol extract of *M. andamanica* demonstrated a significant increase in the hydroxyproline content of the granulation tissue indicating increased collagen turnover. Collagen which is the major component which strengthens and supports extra cellular tissue is composed of the amino acid, hydroxyproline, which has been used as a biochemical marker for tissue collagen (Kumar et al., 2006).

The preliminary phytochemical investigation of the leaf extract showed the presence of tannins, triterpenes and alkaloids. Any one of the observed phytochemical constituents present in *M. andamanica* may be responsible for the wound healing activity. Studies have shown that phytochemical constituents like flavonoids (Tsuchiya et al., 1996) and triterpenoids (Scortichini and Pia, 1991) are known to promote the wound healing process mainly due to their astringent and antimicrobial properties which appear to be responsible for the wound healing and increased rate of epithelialisation (Tsuchiya et al., 1996). The wound healing property of *M. andamanica* may be attributed to the phytochemical constituents present in the plant (Leite et al., 2002). Flavonoids have many therapeutic uses due to their anti-inflammatory, anti-fungal, antioxidant and wound healing properties (Nayak et al., 2009; Zuanazzi et al., 2004; Santos et al., 2004; Okuda, 2005). The quicker process of wound healing could be a function of either the individual or the additive effects of the phytochemical constituents. The early tissue approximation and increased tensile strength of the wound observed in the present study may have been contributed by the tannin content of *M. andamanica*. Tannins are the main components of many plant extracts and they act as free radical scavengers (Bekerecioglu et al., 1998; Marja et al., 1999; Raquel et al., 2000; Andrea et al., 1998; Tran et al., 1996; Dutta and Shastri, 1959). Wound healing activity of the plant may also be subsequent to an associated antimicrobial effect.

Ample numbers of secondary metabolites or active compounds isolated from plants have been demonstrated in animal models as active principles responsible for facilitating healing of wounds. The most important secondary metabolites include tannins isolated from *Terminalia arjuna* (Chaudhari and Mengi, 2006), oleanolic acid isolated from *Anredra diffusa* (Letts et al., 2006), polysaccharides isolated from *Opuntia ficus-indica* (Trombetta et al., 2006), gentiopicroside, sweroside and swertiamarine isolated from *Gentiana lutea* (Ozturk et al., 2006), shikonin derivatives (deoxyshikonin, acetyl shikonin, 3-hydroxy-isovaleryl shikonin and 5,8-Odimethyl acetyl shikonin) isolated from *Onosma argentinum* (Ozgen et al., 2006), asiaticoside, asiatic acid, and madecassic acid isolated from *Centella asiatica* (Maquart et al., 1999; Shukla et al., 1999; Hong et al., 2005), quercetin, isorhamnetin and kaempferol isolated from *Hippophae rhamnoides* (Fu et al., 2005), curcumin isolated from *Curcuma longa* (Jagetia and Rajanikant, 2004).

Overall, the histopathological examination showed that the wound healing process of the wounded tissue in *M. andamanica* leaf extract treated mice was comparably close to the reference drug treated mice. No healing was observed in negative control group. Granulation tissue primarily contains fibroblasts, collagen fibers, very less oedema and newly generated blood vessels which were also observed in the leaf extract treated mice. The histopathological examination provided additional evidence for the experimental wound healing studies which was based on the contraction value of wound area and the measurement of tensile strength. In the present study, the methanolic extract of the aerial parts of *M. andamanica* was found to be remarkably active on excision wound models. Corresponding types of wound-healing effect were reported on many such medicinal plants (Manjunatha et al., 2005; Nayak et al., 2005).

When a wound occurs and is exposed to external environment, it is more prone to attack by microbes which gain entry through the skin and delay the natural wound healing process (Patil and Sunil, 2008). VEGF action is associated with many physiological and pathological neovascular events, such as embryonic development, tumor growth, and wound repair in particular (Ferrara, 1999). During the inflammation phase of healing, neutrophils and macrophages are attracted into the injured tissue by various chemo tactic factors (Hernandez et al., 2001). They locate, identify, phagocytize, kill and digest the microbes and thus eliminate wound debris through their characteristic ‘respiratory burst’ activity and phagocytosis. At higher concentrations, ROS can induce severe tissue damage and even lead to neoplastic transformations which further impede the healing process by causing damage to cellular membranes, DNA, proteins and lipids as well (Loft and Poulsen, 1996; Pryor, 1997). Therefore, if a compound or a plant extract possess antioxidant potentials and antimicrobial activity additionally, it can be a good therapeutic agent for accelerating the wound healing process.

The activity most probably comes from the synergistic effect of compounds present in the extract and also additive effect of hiperisin. According to ethno pharmacological studies, botanical remedies provide two advantages over single compound drugs. Primary active compounds in plants are synergized by secondary compounds and secondary compounds ease the side effects caused by primary active compounds. The course of searching an ethno pharmacologically active plant
extract down to a single active principal ingredient may result in loss of biological activity for a number of reasons. For instance, a special compound may be unstable during the extraction or fractionation or in the purified form.

The fundamental basis of ethno pharmacology does not always exist in a single active compound but rather is a result of the interaction of more than one active compound found in the extract. Sometimes, the single compound potentiates the activity and it may become toxic compared to the whole plant extract. Thus, the likelihood that more than one compound present in the plant extract could contribute to a net pharmacological response of the plant extract.

Conclusion

The present study demonstrated that the aerial parts of *M. andamanica* promote wound healing activity in mice as a preclinical study. The methanolic extract of the leaf showed remarkable wound healing activity and it may be suggested for treating various types of wounds and injuries in animals. The enhanced wound healing activity of *M. andamanica* could possibly be made use of clinically in healing of open wounds. However, confirmation of this study has to be done through well designed clinical evaluation.
