Hypertension accounts for 13% of global mortality, with 25% prevalence in Nigeria. Current trends in management is lifestyle modification. Information on lifestyle habits is needed for effective intervention programs. A study was done among rural dwellers between ages 20 and 75 in Owerre-Nkwoji, Imo State, to determine their knowledge, attitude to hypertension and lifestyle habits. Information gathered would be used to plan an intervention program to increase awareness and promote healthy lifestyles. The study design is descriptive and simple random sampling method was used in selection of village for the study. An instrument used was a questionnaire with sections on background, knowledge, attitude and lifestyle habits. Descriptive and inferential analysis was done. Findings revealed awareness on hypertension as 116 (96.7%). 88 (73%) were aware of sudden death and stroke in the community. Participants with high knowledge were 32 (26.7%), average 40 (33.3%) and low 48 (40.0%). There was positive attitude to hypertension prevention. Sixty-four (53.3%) believed that hypertension can be sent by one’s enemy. Unhealthy lifestyles elicited include use of alcohol, table salt and stimulants. There is a need to correct misconceptions. Readiness for improved health was elicited. As people recognize that lifestyles and behavior significantly affect health, they may assume responsibility for avoiding high risk behaviors.

Key words: Attitude, hypertension, knowledge, lifestyle habits, rural-dwellers.

INTRODUCTION

Hypertension is recorded as a major type of cardiovascular disease which affects one billion people worldwide and claims the life of seven million (American Heart Association, 2006). It accounts for 13% of global mortality (Katib, 2004) with 25% prevalence in Nigeria (Danbauchi, 2007). A current trend in management is lifestyle modification (Simeon and Zieve, 2008). This study serves as a pilot study for a larger study in the same environment. Information on lifestyle habits is needed for effective intervention for health promotion programs. The participants’ knowledge, attitude to hypertension and its preventive measure, lifestyle habits in relation to hypertension as well as blood pressure screening were assessed for this purpose.

MATERIALS AND METHODS

Study was descriptive, done among rural dwellers between ages 20 and 75 in Owerre-Nkwoji, Imo State. The study population was 120 rural dwellers (44 males and 76 females aged between 20 and 75 years). A village was randomly selected out of the six that made up the town through balloting. Informed consent was obtained from the town union leader as well as from each participant. The first household was identified with tossing of the coin at the center of the village square. Elements of the study were drawn from alternate households until the required number was reached. Instrument for data collection were: a structured questionnaire which has four sections that is, demography, knowledge, attitude and lifestyle habits. Measuring tools for blood pressure, weight and height were standardized. Face and content validity was ascertained by experts. Back to back translation was done using 10 respondents from the community to ensure congruence. The measuring tools were tested...
for validity and reliability before putting them into use. Blood pressure, weight and height measurements were recorded with appropriate tools. All questionnaires were retrieved as it was interview administered, through training research assistants. Data when validated was found to be congruent. Analysis of Cronbach’s alpha for English 1, Vernacular (Igbo) and English 2 was 0.63. Reliability of tool using Cronbach’s coefficient was computed and value was 0.76. Data was entered using statistical package for social sciences 17.0. Descriptive analysis was done which displayed the frequencies of various variables; the mean values as well as the standard deviation (SD). Body mass index (BMI) and blood pressure classification was done. Inferential analysis of association between dependent and predisposing variables were computed using Chi square.

**RESULTS**

Age ranged from 20 to 75 (mean 36, SD ± 12.83). Sixteen (13%) had no formal education; 20 (17%) primary; 48 (40%) secondary and 36 (30%) had tertiary education. Seventy six (63%) were jobless; 24 (20%) civil servants; 12 (10%) farmers; 8 (7%) are petty traders. Household income; lower class was 68 (57%), lower middle class was 48 (40%), and middle class was only 4 (3%). None were upper class. The overall awareness level was 44%. Findings revealed that 116 (96.7%) were aware that the term “hypertension” refers to high blood pressure. Twenty four (20%) were aware of their blood pressure readings while 96 (80%) are unaware. Responses on awareness of incidents of stroke and sudden deaths in the community was 88 (73.3%) each. Overall knowledge was 60%. Knowledge were 32 (26.7%), average 40 (33.3%) and low 48 (40.0%). Knowledge of stroke as a complication of hypertension: Yes; 36 (30.0%); No 8 (6.7%) while ‘do not know’ was 76 (63.3%).

There was a positive attitude to hypertension prevention. Sixty eight (56.7%) strongly agreed and 52 (43.3%) agreed that hypertension is of serious health concern. Twenty (16.7%) strongly agreed and 52 (43.3%) agreed that it is important to check one’s blood pressure regularly even though 16 (13.3%) strongly agreed and 36 (30.0%) agreed that hypertension is not for young people.

Unhealthy lifestyles elicited include use of alcohol, table salt and stimulants (Figure 1). The relationship between age and knowledge was not significant; Pearson $X^2 = 0.563$, P-value = 1.151.

DISCUSSION

Awareness of participants on hypertension issues was 44% as against the 50% in the study by Ike et al. (2010). Misconception was also apparent in this study as in theirs. For example, stroke and hypertension can be caused by gods or enemy, respectively. Attitude to hypertension was negative especially among participants, as majority strongly disagreed with having hypertension in their lifetime and does not affect young people. Apparently these participants will not go for a routine blood pressure check based on their belief. It was also noted that majority of the participants could not differentiate between daily activities and regular exercise as it was strongly agreed that daily activities was same as regular exercises unlike in the study by Ohata et al. (2005) where all participants appreciated a 12 week reading. BMI showed participants were not obese (Figure 2).
regular exercise as an intervention. Identified risk factors were in line with Wang et al. (2006) and Omorogiwa et al. (2009) in their studies. Smoking was not identified as a risk factor as in the report by Ricks (2004) and Aghaji (2008) but snuff was enlisted. The unhealthy lifestyles in relation to nutrition include the chewing of kolanut, use of table salt, and alcohol as in the studies by the aforementioned researchers.

Conclusion

Even though majority was aware that the term 'hypertension' refers to high blood pressure, the overall level of awareness was poor. Majority agreed that hypertension is a serious ailment and that adoption of healthy lifestyles will curb the menace, which implies that there would be health seeking behavior among the population. Myths about hypertension need urgent intervention. The findings of this study cannot be generalized because of the population size. There is therefore need for population focus study. Information gathered would be used to plan an intervention programme to increase awareness and promote healthy lifestyles.
